1 Pleas in the District Court of the United States for the District of Colorado, Sitting at Denver.

Be It Remembered, that heretofore, and on, to-wit, the twenty-ninth day of April, A. D. 1914, came the Denver Union Water Company by Gerald Hughes, Esquire, and Clayton C. Dorsey, Esquire, its solicitors, and filed in said court, its bill of complaint; and sued out of and under the seal of said court a subpœna in chancery against The City and County of Denver, J. M. Perkins, Clair J. Pitcher, Alexander Nisbet, John B. Hunter and Otto F. Thum, as Commissioners, members and constituting the Council, of the City and County of Denver; J. M. Perkins, as Mayor and Commissioner of Social Welfare of the City and County of Denver; Clair J. Pitcher, as Commissioner of Finance of the City and County of Denver; Alexander Nisbet as Commissioner of Safety of the City and County of Denver; John B. Hunter, as Commissioner of Improvements of the City and County of Denver; Otto F. Thum, as Commissioner of Property of the City and County of Denver; James F. Markey, as Auditor of the City and County of Denver; Armour C. Anderson, Edwin Van Cise and A. Lincoln Fellows, as members of and constituting the Public Utilities Commission of the City and County of Denver.

2 And the said bill of complaint is in words and figures as follows, to-wit:

In the District Court of the United States within and for the District of Colorado.

In Equity. No. —.

THE DENVER UNION WATER COMPANY, a Corporation, Complainant,

vs.

THE CITY AND COUNTY OF DENVER, a Corporation; J. M. PERKINS, Clair J. Pitcher, Alexander Nisbet, John B. Hunter and Otto F. Thum, as Commissioners, Members of and Constituting the Council of the City and County of Denver; J. M. Perkins, as Mayor and Commissioner of Social Welfare of the City and County of Denver; Clair J. Pitcher, as Commissioner of Finance of the City and County of Denver; Alexander Nisbet, as Commissioner of Safety of the City and County of Denver; John B. Hunter, as Commissioner of Improvements of the City and County of Denver; Otto F. Thum, as Commissioner of Property of the City and County of Denver, James F. Markey, as Auditor of the City and County of Denver; Armour C. Anderson, Edwin Van Cise and A. Lincoln Fellows, as members of and constituting the Public Utilities Commission of the City and County of Denver, Defendants.

Bill of Complaint.

3 To the Honorable the Judges of the District Court of the United States for the District of Colorado:

The Denver Union Water Company, a corporation, as hereinafter stated, brings and files this bill of complaint against the city and

county of Denver, a municipal corporation; J. M. Perkins, Clair J. Pitcher, Alexander Nisbet, John B. Hunter and Otto F. Thum, as Commissioners, members of and constituting the council, of the City and County of Denver; J. M. Perkins, as Mayor and Commissioner of Social Welfare of the city and county of Denver; Clair J. Pitcher, as Commissioner of Finance of the city and county of Denver; Alexander Nisbet, as Commissioner of Safety of the city and county of Denver; John B. Hunter, as Commissioner of Improvements of the city and county of Denver; Otto F. Thum, as Commissioner of Property of the city and county of Denver; James F. Markey, as Auditor of the city and county of Denver; Armour C. Anderson, Edwin Van Cise, and A. Lincoln Fellows, as members of and constituting the Public Utilities Commission of the City and County of Denver; and complains and avers as follows:

First. Complainant is and was at all the times hereinafter mentioned, since October 18th, 1894, a corporation duly incorporated, organized and existing and doing business under and by virtue of the laws of the State of Colorado, and having its principal
4 office and place of business in the city and county of Denver, in said state; that in, by and under its articles of incorporation, and by virtue of full compliance with the laws of the state of Colorado in such case made and provided, it is now, and ever since said date has been, authorized and empowered by the State of Colorado to acquire, construct, extend, own, maintain and operate, water works for and engage in the business of supplying water to the city and county of Denver, and its included municipalities and territories, and all of the inhabitants thereof, for all uses and purposes, and to take tolls and rates therefor; and to acquire, own, maintain and operate such property as may be necessary or convenient for said purposes, and in the prosecution of such business to place, maintain and operate in the roads, streets, alleys and public places of the city and county of Denver and elsewhere, its pipes, mains, conduits and other apparatus constituting its plants or system for the supplying of water to and in said city and county of Denver.

Second. The defendants, the city and county of Denver, a municipal corporation existing under and by virtue of Article XX of the Constitution of the State of Colorado, J. M. Perkins, Clair J. Pitcher, Alexander Nisbet, John B. Hunter and Otto F. Thum, as Commissioners, members of and constituting the Council of the city and county of Denver; J. M. Perkins, as Mayor and Com-
5 missioner of Social Welfare of the city and county of Denver; Clair J. Pitcher, as Commissioner of Finance of the city and county of Denver; Alexander Nisbet, as Commissioner of Safety of the city and county of Denver; John B. Hunter, as Commissioner of Improvements of the city and county of Denver; Otto F. Thum, as Commissioner of Property of the city and county of Denver; James F. Markey, as Auditor of the city and county of Denver; Armour C. Anderson, Edwin Van Cise and A. Lincoln Fellows, as members of and constituting the Public Utilities Commission of the city and county of Denver; are each and all of them residents and citizens

of the city and county of Denver, having their principal offices and places of business in the city and county of Denver, in said state of Colorado.

Third. This is a suit of a civil nature in equity arising under the Constitution and laws of the United States, to-wit: Those provisions of the Constitution of the United States and amendments thereto, hereinafter specifically mentioned and referred to, and the matter in dispute exceeds exclusive of interest and costs, the sum of five thousand dollars ($5,000.00).

Fourth. The Denver Union Water Company was incorporated and organized under the laws of the state of Colorado on October 18th, 1894, with an authorized capital stock of seven million, five hundred thousand dollars ($7,500,000.00), divided into five
6 million dollars ($5,000,000.00) par value, of common stock, and two million five hundred thousand dollars ($2,500.-000.00) par value, of preferred stock, all of which stock was on the organization of said Company issued in part payment for property then acquired by complainant, and is now, and at all times since said original issuance has been, issued and outstanding. At the time of its organization The Denver Union Water Company became the successor in interest of and the owner and possessor of, all of the property theretofore belonging to The Citizens Water Company, The Beaver Brook Water Company, The Mountain Water Company, The American Water Works Company of New Jersey, The Denver City Water Works Company, The Domestic Water Company, The Denver Water Company, The Denver City Irrigation and Water Company, and The Denver City Water Company, and now is the owner of such property, together with the additions, extensions, betterments and improvements which have from time to time been acquired or constructed and added thereto. The companies above mentioned in this paragraph whose property The Denver Union Water Company acquired constituted all of the various companies which had furnished water to the city and county of Denver and its inhabitants from 1870 to the date of the organization of The Denver Union Water Company. The property above de-
7 scribed, now owned by The Denver Union Water Company, constitutes, and at the time of its acquirement, and ever since has, constituted all of the property used in the supplying of the city and county of Denver and the inhabitants thereof with water.

Complainant on October 20th, 1894, executed and delivered to Continental Trust Company of the city of New York, as Trustee, its certain mortgage or deed of trust, securing a bond issue of eight million dollars ($8,000,000.00), bearing interest at the rate of five per cent (5%) per annum, and maturing July 1, 1914, which said mortgage or deed of trust was recorded in the records of the office of the Clerk and Recorder of the city and county of Denver, then the county of Arapahoe, on the 1st day of November, A. D. 1894, in book 1023, at page 28, and thereafter, in accordance with the terms of said mortgage all of said eight million dollars ($8,000,-000.00) of bonds were duly issued, and ever since have been and are now outstanding in the hands of bona fide purchasers for value.

Since the date of the execution of said mortgage the New York Trust Company has succeeded the said Continental Trust Company as Trustee under said mortgage.

Since the organization of complainant in 1894 the complain-t has paid and distributed to its stockholders, the following dividends and no others:

8

Year.	Dividend.
1894	0%

Total	15%

With the exception of the dividends paid and distributed to stockholders of complainant in the years 1905, 1906 and 1907, all of the net earnings and surplus of complainant earned and accumulated during its existence have been used and devoted to the purchasing and acquiring of additional property, to the extension, improvement and betterment of the properties and water system owned by complainant and used for supplying the city and county of Denver and its inhabitants with water, and for the protection and preservation of said properties and the business of complainant.

Fifth. Defendant, the city and county of Denver, is a municipal corporation existing under and by virtue of Article XX of the Constitution of the state of Colorado, and now has, and since February 14th, 1913, has had, a charter which provides what is com-

9 monly called a "Commission Form of Government" for the city and county of Denver, under which the powers and duties of the legislative, executive and administrative departments are vested in five commissioners. The defendants, J. M. Perkins, Clair J. Pitcher, Alexander Nisbet, John B. Hunter and Otto F. Thum, are the duly elected, qualified and acting Commissioners of the city and county of Denver, each being a member of, and together con-

stituting the Council of the city and county of Denver. J. M. Perkins is the duly elected, qualified and acting Commissioner of Social Welfare of the city and county of Denver, and also Mayor thereof; Clair J. Pitcher is the duly elected, qualified and acting Commissioner of Finance of the city and county of Denver; Alexander Nisbet is the duly elected, qualified and acting Commissioner of Safety of the city and county of Denver; John B. Hunter is the duly elected, qualified and acting Commissioner of Improvements of the city and county of Denver; Otto F. Thum is the duly elected, qualified and acting Commissioner of Property of the city and county of Denver; James F. Markey is the duly elected, qualified and acting Auditor of the city and county of Denver; Armour C. Anderson, Edwin Van Cise and A. Lincoln Fellows claim to be and are acting as the duly elected and qualified members of the Public Utilities Commission of the city and county of Denver. The Public Utilities Com-
10 mission and the members thereof, as above alleged, derive their power from and are now acting under Section 264-A of the Charter of the city and county of Denver as adopted on May 17th, 1910.

Under Article XX of the Constitution of the State of Colorado, the defendant, the city and county of Denver, is the legal successor of the City of Denver, and the towns of Barnum, Colfax, Harmon, Highlands, South Denver, Argo, Berkeley, Elyria, Globeville, Montclair and Valverde, and embraces within its exterior boundaries all of the territory theretofore embraced in each and all of said predecessor municipalities, and includes approximately 37,920 acres.

Sixth. In 1870 The Denver City Water Company began the construction of a waterworks system to supply the city of Denver and its inhabitants with water. Prior to the organization of The Denver Union Water Company in 1894 and the acquirement by it of the properties of its grantor companies, as set forth in Paragraph Fourth of this bill, said grantor, and predecessor companies had constructed water systems for supplying the different municipalities which were afterwards consolidated into the city and county of Denver. Upon the organization of complainant, The Denver Union Water Company, in 1894, when it acquired all of the properties and water sys-
tems of its grantor companies, it united said properties and
11 systems into one system, which since said time has been operated as a unit and has been and is now the sole and only source of water supply for all purposes for the city and county of Denver and its inhabitants.

In 1870 the City of Denver, according to the United States census of that year, had a population of 4,759 persons, which population has constantly increased since that time, as shown by the United States census, so that in 1880 the population was 35,629; in 1890, 106,713; in 1900, 133,859; in 1910, 213,381. The commercial, financial and material growth of the said City of Denver has at all times increased correspondingly to its increase in population, and the demands on the complainant and its grantor companies likewise correspondingly increased in connection with the supplying of water to the defendant the city and county of Denver, its predecessor municipalities and the inhabitants thereof, for all purposes. In order

to meet the increased requirements of the defendant the city and county of Denver, and its predecessor municipalities, the complainant and its grantor companies, have from time to time from 1870 to date added to their properties, expanded their water systems and expended large sums of money in connection therewith.

At the present time and for some years last past the properties of the complainant constitute a complete and efficient water
12 supply system for the city. It embraces every element of structure and equipment found in any water system together with many additional important elements necessitated by peculiar local conditions found only in semi arid regions, and the water supply is obtained under different conditions than apply in any large city in the country.

For more than forty years the complainant or its grantors have been acquiring by appropriation and purchase the early water rights above Denver that can be advantageously used for a water supply for the city. They have constructed huge storage reservoirs capable of impounding sufficient water to meet the present requirements of the city, and any reasonable immediate growth, without replenishing or without aid from any other source.

Through these operations they have developed a water supply ample for all the needs and requirements of the city and county of Denver and its inhabitants, with rights perfected for use all the year around instead of for the crop growing season as is the case of irrigation rights and of such magnitude as to control during a considerable portion of every year all of the water flowing in the streams above Denver in the non-irrigating season. Because of the fact that it is impossible to obtain at any one place on any one stream above Denver a water supply adequate for its means, the supply of the com-
13 plainant is diverted at six separate and distinct locations on the South Platte River, Bear Creek and Cherry Creek at distances ranging from three to forty-eight miles from the city.

The principal physical properties of the water system consists of the following important items:

First. Eleven storage sedimentation and distribution reservoirs with controlling equipment and machinery, having an aggregate capacity of thirty-three billion gallons.

Second. Two reservoir sites partly constructed and which, when completed, will have an aggregate capacity of more than ten billion gallons.

Third. Six separate and distinct diversion systems with dams, headgates, galleries, cribs and other equipment.

Fourth. Three large and efficient filtration plants having an aggregate capacity of 65 million gallons daily.

Fifth. 532.45 miles of distributing mains and conduits ranging from four inches to sixty inches in diameter, with valves, fire hydrants and other necessary equipment, including seven large conduits ranging from three and one-half miles to twenty-two miles in length, and thirty inches to sixty inches in diameter, used to bring, by gravity, water from the reservoirs and filtration plants to the dis-

tribution system. More than forty per cent. of the total mileage of pipes and conduits is twelve inches or larger in diameter.

14 Sixth. Six large pumping stations having an aggregate capacity of sixty four million gallons daily.

Seventh. More than thirteen thousand acres of land used and necessary in connection with the control of water rights, protection of water supply and location of plant structures.

The above description is not complete or detailed, and is intended only to show the general extent and character of complainant's property.

Defendant, the city and county of Denver, is located in a semi arid region, at the eastern base of the Rocky Mountains, and dependent entirely for its water supply upon the small mountain streams which flow through or near it. The entire agricultural region surrounding and adjacent to defendant the city and county of Denver, is likewise dependent upon the water from said mountain streams for the irrigation thereof and in connection with the raising of crops thereon. As the population of defendant, the city and county of Denver has increased, and also the population of the surrounding and adjacent country, the demand for water has correspondingly increased until all of the available water has, for some years last past, been appropriated and is being used for domestic and irrigation purposes. Defendant, the city and county of Denver, has

15 not now, and never had, any source of water supply for itself and its inhabitants, or any water system or property for the distribution thereof.

Seventh. Since the formation of the complaint in 1894 all of its property acquired from its grantor companies, together with all additions, extensions, betterments and improvements thereto, has been devoted to the necessary and actual use of supplying the defendant the city and county of Denver and its inhabitants with water for all purposes, and the complainant has constantly and from time to time added to its properties and its water system and plant as the needs of the defendant the city and county of Denver and its inhabitants manifested themselves.

Complainant acquired from The Denver Water Company a certain franchise, known as Ordinance No. 44 of 1890, by some of the terms of which said The Denver Water Company and its assigns were entitled to occupy all of the streets and public ways of said City of Denver, and to supply said City of Denver and its inhabitants with water, and to charge therefor a certain schedule of rates, which said schedule of rates was in said ordinance and has always been identified as "Schedule A," and under which ordinance No. 44 of 1890 complainant supplied water to the city and county of Denver and its inhabitants until April 10th, 1910, and until in a suit in the Circuit

16 Court of the United States within and for the district of Colorado, entitled, "The New York Trust Company, a corporation, complainant, vs. The City and County of Denver, a municipal corporation, et al., defendants, in Equity, No. 5572," certain rights and privileges of complainant thereunder were held to have terminated.

Eighth. Schedule "A" has at all times been the basis of the schedule of rates charged by complainant, but from time to time the charges and rates and terms thereunder have been modified, reduced and made more favorable to defendant, the city and county of Denver, and in 1895 a horizontal reduction was made in the items contained in said Schedule "A", which resulted in a new schedule, following in items said Schedule "A", known as the "Leaflet Schedule", which is as follows:

The Denver Union Water Company.

Schedule of Semi-Annual Water Rates.

Payable in advance on the first days of May and November in each year, at the office of the Company, 501 17th, Cor. of Glenarm St.

To take effect November 1, 1895.

Alcohol, each barrel manufactured		$.04
Ale cellar	$8.00 to	16.00
Bakery, each oven	4.00 to	20.00
Barber shop, first chair		3.20
Barber shop, each additional chair		1.20
Barber baths, each		6.00
Bath, in private house, with heating apparatus:		
First bath tub		2.00
Each additional tub		1.20
17 Bath, private house, without heating apparatus		$.80
Bath, in boarding or tenement house of 15 rooms or less		2.00
Bath, in boarding or tenement house of over 15 rooms		4.00
Bath, public, hotel, saloon, sporting house, restaurant or club house, not less than		4.00
Beer, each barrel brewed		.04
Beer house	8.00 to	16.00
Beer pump, not less than		4.00
Billard tables, each		1.20
Boarding or tenement house, per room		.60
But no license less than		4.00
Book bindery not less than		4.00
Bowling alley, not less than		4.00
Bottling works	10.00 to	16.00
Brick work, per 1,000 kiln count		.08
Brick yard, each gang of hands		8.00
Camphene, each barrel manufactured		.04
Candle manufactory	20.00 to	200.00
Candy manufactory	4.00 to	30.00
Church	2.00 to	6.00
Church, Baptist for baptistry	2.00 to	6.00
Cigar manufactory, per hand		.08
But no license less than		4.00
Club room	12.00 to	40.00

Coffee saloon	6.00 to	12.00
Confectionery	6.00 to	24.00
Concrete, per cubic yard		.08
Concrete, per cubic yard, street paving		.06
Cow		.40
Cows, over five head, each		.30
Distillery, each barrel distilled		.04
Dram shop or saloon	$10.00 to	$30.00
Dyeing and scouring	10.00 to	30.00
Forge		1.20
Fountain, for six months, running not more than four hours per day:		
1 opening 1–16 inch diameter		12.00
1 opening 1–8 inch diameter		20.00
1 opening 3–16 inch diameter		32.00
1 opening 1–4 inch diameter		40.00
1 opening 5–16 inch diameter		48.00
1 opening 3–8 inch diameter		60.00
1 opening 7–16 inch diameter		72.00
1 opening 1–2 inch diameter		96.00
Fountain, vegetable	6.00 to	10.00
Fountain, fish	20.00 to	32.00
Fountain in drug store, opening not to exceed 1–8 inch in diameter		32.00
Hall	2.00 to	12.00
Hat manufactory	6.00 to	30.00
Horse, in private stable		1.20
Hose, for livery or sale stable, not less than		16.00
Hose, for livery stables:		
Not over 25 single stalls		16.00
Over 25 and up to 40 single stalls		20.00
Over 40 and up to 50 single stalls		30.00
Over 50 single stalls		40.00
Hotel, per room		.60
Ice cream saloon	6.00 to	16.00
Laboratory	8.00 to	40.00
Laundry	8.00 to	120.00
Laundry Chinese, not less than		10.00
Livery stable, per stall		.80
Lunch, in saloons	6.00 to	12.00
Malting, per 100 bushels		.80
Motor for church organ	10.00 to	16.00
Office and banks	2.00 to	12.00
Oyster saloon	6.00 to	12.00
18 Packing house	$16.00 to	$200.00
Photograph gallery	8.00 to	16.00
Plastering, per 100 square yards		.40
Porter cellar	8.00 to	16.00
Rectifying whisky, per 100 barrels		2.40
Residence, occupied by one family only:		

1 to 4 rooms		2.00
5 or 6 rooms		2.40
7 or 8 rooms		2.80
9 or 10 rooms		3.20
11 or 12 rooms		3.60
13 or 14 rooms		4.00
15 or 16 rooms		4.40
17 or 18 rooms		4.80
19 or 20 rooms		5.20
Residence used as boarding or tenement house of 10 or more rooms, per room		.60
Residence used as boarding or tenement house of less than 10 rooms		4.00
Rooms in blocks or over business houses		.60
Restaurant	$10.00 to	40.00
Sale stable, per stall		.80
But no license less than		16.00
School, including all uses of water except for boilers, motors and irrigation, for every scholar		.06
Store rooms and shops	2.00 to	120.00
Store rooms and shops:		
12½ feet front or less		2.00
Over 12½ feet front to 18 feet front		3.20
Over 18 feet front to 25 feet front		4.80
Over 25 feet front to 37½ feet front		6.00
Over 37½ feet front to 50 feet front		8.00
Over 50 feet front, special rates.		
Stores:		
Confectionery store	6.00 to	16.00
Drug store	6.00 to	12.00
Liquor store	6.00 to	12.00
Meat store or butcher shop	6.00 to	12.00
Saloons	10.00 to	30.00
Slaughter house	10.00 to	200.00
Soap manufactory	40.00 to	300.00
Soda manufactory	16.00 to	80.00
Sprinkling and washing pavements or side walks where irrigation rates are not paid, per foot run		.08
Starch manufactory	20.00 to	80.00
Steam boilers, running 24 hours per day per square foot of fire surface		.16
But no license less than		10.00
Steam boilers, for heating buildings or tenement houses only, per square foot of fire surface		.04
But no license less than		8.00
Steam boiler, for heating private residence		4.00
Stock yard	10.00 to	200.00
Stone work, per perch		.04
Sugar refinery	120.00 to	1,200.00
Tannery, per vat		2.40
But no license less than		**10.00**

Tenement, per room		.60
But no license less than		4.00
Tobacco manufactory, per hand		.80
But no license less than		4.00
Tumbler washer in drug store		32.00
Urinal basin or trough	2.00 to	8.00
Vault, for residence		1.60
Vault, accommodating double house or more than one tenant, each tenant		1.20
Vault, for tenement or boarding house for every 15 rooms or less		2.00
Vault for bar room or saloon		2.00
Vinegar, for each barrel manufactured		.04
Washing bottles	$2.00 to	8.00
Washing barrels, per barrel		.04
Washing meat	20.00 to	200.00
Washing vehicle in private stable, not less than		2.00
Water closet, private house, first bowl		2.00
Water closet, private house, each additional bowl		1.20
Water closet, in boarding or tenement house of 15 rooms or less		2.00
Water closet, in boarding or tenement house of over 15 rooms		4.00
Water closet, in hotel, club room, restaurant, saloon, barber shop or sporting house		4.00
Water closet, for use of two or more stores or houses		4.00
Wine cellar	8.00 to	16.00

Special Rates.

Irrigation of lots, including sidewalk and trees, only through hose with nozzle not to exceed one-quarter of one inch in diameter, to be used only within the hours specified on the license and never during a fire or conflagration, 22 cents per front foot for the season. Where irrigation is used outside of property line along the side of irrigated corner lots, the frontage is counted to include one-half lot additional. No license for irrigation will be issued for less than the season rate.

Meter and Elevator Rates.

Payable Monthly.

1,000	to	15,000	gallons	per	month,	20	cents	per	1,000 gallons.
15,000	to	30,000	"	"	"	18	"	"	" "

150,000	to	315,000	"	"	"	12	"	"	" "
315,000	to	637,500	"	"	"	11	"	"	" "
Over		637,500	"	"	"	10	"	"	" "

Minimum meter and elevator rate for business premises $3.00 per month.

Minimum meter rate for residences, 25 cents per month.

Where water is paid for all purposes on premises, there will be no additional charge for a standpipe for fire protection.

Where the Denver Union Water Company's water is not used, a special rate will be made for such standpipes.

20 With the exception of the years 1898 to 1907, during which time rates were in effect slightly in excess of said Leaflet Schedule, except as to meter rates, as provided by a certain decree of the District Court of the state of Colorado for the Second Judicial District, entitled "The City of Denver vs. The Denver Union Water Company, No. 26251," said Leaflet Schedule has been in full force and effect, including the years 1909, 1910, 1911, 1912, and 1913.

By ordinance 44 of 1890, it was provided, in reference to charges for hydrants to be paid by the city of Denver:

"For the period of ten years from and after the first day of May, 1891, the sum of thirty-five dollars per hydrant per annum for all hydrants then set and in operation, and for the remaining period until the right of purchase shall accrue, as mentioned in section 11 thereof, the sum of twenty-five dollars per hydrant per annum for all hydrants then set and in operation. All payments by the city to be made semi-annually on the first days of May and November in each year during the period aforesaid, at the office of the city treasurer."

The charges made by complainant to, and paid by defendant, the city and county of Denver and its predecessor the City of Denver, for hydrant rental, has been as follows:

Years.	Rate per hydrant per year.
1891-1901	$35.00
1901-1910	25.00
1910-1914	22.50

But the said payments for the years 1910, 1911, 1912,
21 1913 and 1914 have been accepted by the complainant with the reservations of the right to claim an additional and reasonable rate per hydrant, which said claim has never been surrendered or waived.

Ninth. Water is a commodity having an ascertained value in the city and county of Denver and State of Colorado, daily increasing in value as the uses are increased, and it is, and for many years has been necessary that the needs of the defendant the city and county of Denver for water should be anticipated, and that such water supply should be several years in advance of the actual present need, and unless such water were acquired, held and used not only would the future growth of the city and county of Denver be impeded, but its present welfare and safety seriously affected. At certain periods of each year all of the natural flow of the streams supplying

water to the city and county of Denver are not sufficient to supply one-half of the actual daily consumption, and therefore it is and has been essential in order to supply the defendant City and its inhabitants with water and to protect their health and safety, that large storage reservoirs should be built and maintained on the head waters of such streams above Denver, all of which has heretofore been done by complainant and cannot now be duplicated upon said streams. Among other things, one of complainant's grantor
22 companies heretofore caused to be incorporated The South Platte Canal and Reservoir Company, a Colorado corporation, with a capital stock of five hundred thousand dollars ($500,000.00), and all of the capital stock of said The South Platte Canal and Reservoir Company is now and has for many years been held and owned by complainant. Said The South Platte Canal and Reservoir Company, acting under the control of complainant, by the expenditure of large sums of money obtained and furnished by and through complainant, heretofore constructed a dam and created a reservoir, known and designated as the "Cheesman Lake and Dam" on the South Fork of the South Platte River, approximately forty-eight miles distant from the city and county of Denver, and which was constructed and has been and is used and necessary to be used as a storage reservoir to impound and store water for the supplying of the defendant City and its inhabitants through the water-works system of complainant, and other purposes, which reservoir has a capacity of 25,761,407,322 gallons, and now contains said amount of water, being a sufficient amount to meet the demands of the city and county of Denver; to permit of its future growth and to protect the health and safety of said city and county of Denver and its inhabitants.

Said Cheesman lake and reservoir is located twenty-three miles distant from the nearest railway point, and all material and
23 supplies used in its construction, except sand and granite, had to be hauled in by wagon from said nearest railway point. The dam of said Cheesman lake and reservoir is constructed of solid granite masonry, laid with cement; is two hundred and thirty-six (236) feet high; one hundred and seventy-six (176) feet wide at the base, and eighteen (18) feet wide at the top; thirteen hundred and eight (1308) feet long and required eighty-three thousand (83,000) barrels of cement in its construction, and more than five years to complete. There are three outlet tunnels through the solid granite shoulders of said dam, equipped with valves and machinery for the operation thereof, and the complete control of the outflow of said reservoir. The surface area of said reservoir is eight hundred and seventy-nine (879) acres and The South Platte Canal and Reservoir Company acquired and owns eight thousand, four hundred and thirty-six (8,436) acres surrounding and adjacent to said reservoir, used and necessary to be used to protect said lake and reservoir and the water therein contained, from contamination.

Said The South Platte Canal and Reservoir Company under the direction and control of complainant, also acquired and owns a

large amount of other property, including water and water rights, filter beds, filtration plants, conduits, diversion dams and works, and other like holdings, all of which were so acquired as
24 and are an essential part of the waterworks system of complainant, and are used and necessary to be used for the water supply of the city and county of Denver and its inhabitants.

The South Platte Canal and Reservoir Company, in order to so acquire and construct said above described property and to pay therefor, authorized an issue of its bonds in the aggregate sum of four million dollars ($4,000,000.00), bearing interest at the rate of five per cent (5%) per annum from the date thereof, and running for the period of twenty (20) years from their date, to-wit, July 1st, 1903; and to secure the payment thereof made, executed and delivered to the Morton Trust Company of New York, as Trustee, its deed of trust or mortgage on all of its property, real and personal, rights and franchises, then acquired and thereafter to be acquired; and complainant agreed to and did guarantee the payment of both principal and interest of each and all of said bonds. All of said bonds have heretofore been issued and sold, and in good faith purchased, and are now outstanding in the hands of purchasers for value.

On May 1st, 1903, The South Platte Canal and Reservoir Company made and entered into an agreement of lease with complainant, wherein and whereby it leased, let and demised unto said complainant, for the period of twenty (20) years from and after July 1st, 1903, all of its property of every kind, then owned or
25 thereafter to be acquired, with the right in complainant to use and operate the same, and with the exclusive right to the use of all water belonging to said The South Platte Canal and Reservoir Company, and ever since said last named date complainant has been and now is in full possession, control and use of all of said property of The South Platte Canal and Reservoir Company, and the same is used and necessary to be used as, and constitutes an essential and integral part of the water-works system of the complainant, devoted to the supplying of water to the city and county of Denver and its inhabitants.

Under said lease complainant was obligated to operate and maintain said properties of The South Platte Canal and Reservoir Company, and to pay all operating costs, taxes, and interest on its bonds. Said lease obligations have at all times been performed and are now being performed by complainant, and the properties are operated and used as a unit with complainant's properties.

Tenth. In October, 1907, complainant, at the request of defendant, the city and county of Denver, entered into arrangements with said city and county of Denver for the appraisement of all of the property of the complainant, including the property of The South Platte Canal and Reservoir Company, and in order to carry out said arrangement defendant, the city and county of Denver,
26 caused Ordinance No. 163 of the Series of 1907 to be prepared and enacted, approved and published as an Ordinance

of said city and county of Denver, which said Ordinance No. 163 of the Series of 1907, is as follows, to-wit:

By Authority.

Ordinance No. 163. Series 1907.

Aldermanic Bill No. 110.

Introduced by Ald. Bush.

A bill for an ordinance authorizing and empowering the city and county of Denver to enter into a contract with The Denver Union Water Company, whereby said company shall agree that the city and county of Denver may purchase the property of said company under an appraisement to be made in accordance with section 11, of ordinance No. 44, of the Series of 1890, before the arrival of the time fixed therefor in said contract, and authorizing the appointment of appraisers by a committee composed of the mayor, the president of the board of supervisors and the president of the board of aldermen in accordance with the provision for an appraisement of said property in the manner provided for in said Section 11 of Ordinance No. 44, of the Series of 1890, and to determine the fair and reasonable value of the water plant of said The Denver Union Water Company, and the corporations and persons used by said The Denver Union Water Company in supplying water to the city and county of Denver and to the inhabitants of the said city and county of Denver, and prescribing the manner of executing and carrying out such contract.

Whereas, on April 10th, 1890, a contract was made and entered into between the City of Denver and The Denver Water Company, contained and set forth in Ordinance No. 44 of the Series of 1890, which was duly enacted, granting The Denver Water Company the right of laying down, continuing and maintaining water pipes, valves, hydrants and apparatus for the conveyance and distribution of water through the streets, alleys and public places of said city, for the use of said city, and the inhabitants thereof; and

Whereas, in and by said contract so contained in said ordinance, it is provided in Section 11 thereof, that:

"At the expiration of the period of twenty years from and after the date of the passage and approval of the ordinance, in case the city shall then elect so to do, the said works may be purchased by the said city, and in case the parties cannot agree, after such election, upon the price to be paid by the city for the water works of the said company, its successors and assigns, then their fair cash value shall be determined by arbitration, by five disinterested persons, none of whom shall be residents of Denver, two of them to be chosen by the City, two by the company, and the fifth by the four first chosen, and in case of failure on the part of the company to name arbitrators for the period of thirty days after the city shall have named arbi-

trators and notified the company so to do, the city may apply to any court having equity jurisdiction in the county in which the City of Denver shall then be situated for the appointment of two persons of the qualifiactions aforesaid as such arbitrators, and the court may thereupon appoint two such persons, who shall act with the same force and effect as if appointed by the company, and the decision of a majority of said board shall be final and binding upon both parties, and upon the payment, or tender of payment, by said city the said company shall convey to said city all of its property, real or personal, easements, rights and privileges and thereafter all franchises, rights and privileges which have been at any time theretofore granted said company, its successors or assigns, and which it may then possess, shall cease and be at an end."

And Whereas, The Denver Union Water Company has become the owner of the properties and franchises of the said The Denver Water Company, and is at the present time its successor in and the holder of the said contract set forth and contained in said Ordinance No. 44 of the Series of 1890, aforesaid; and,

Whereas, Section 5 of the Ordinance No. 44 of the Series of 1890, provides that:

"The rate to private consumers for water shall not be greater than now charged by the said The Denver Water Company, a schedule of which rates is hereto annexed marked Schedule A, and the said The Denver Water Company may require any consumer to furnish a meter and pay for water by meter measurement; Provided, however, That, at any time after five years from date, the city council may require said company to fix schedule rates for private consumers equivalent to the average rates prevailing in the cities of Chicago, St. Louis and Cincinnati for the same service."

And, Whereas, it has been deemed desirable that efforts should be made by and on behalf of the City and County of Denver to purchase the water plant and property owned and used by The Denver Union Water Company in supplying water to the City and County of Denver and the inhabitants thereof, in accordance with the terms and provisions of the said contract of April 10, 1890, and upon a valuation thereof fixed by disinterested appraisers selected in accordance with the terms of said contract; and,

Whereas, the Mayor of the City and County of Denver, at the request of the members of the Council of the City and County of Denver, entered upon negotiations with The Denver Union Water Company for the purpose of ascertaining whether or not said appraisement might be made and said purchase effected before the time fixed in and by the terms of said contract—the said The Denver Union Water Company waiving the right to insist that said purchase could not be made under the terms of said contract until after the expiration of the period fixed therefor in the paragraph thereof, hereinbefore quoted: and,

Whereas, a correspondence was conducted between the said Mayor of the City and County of Denver and the said The Denver Union Water Company, copies of which have been heretofore transmitted

to the Council of the City and County of Denver, and considered by said Council; and,

Whereas, said The Denver Union Water Company has an abundant supply of water at all seasons of the year for the present and future needs of the City and County of Denver and its inhabitants, but admits that from time to time additions must be made to the conduits and pipes used in conducting and distributing said supply, and that in view of the shortness of the time which will elapse before the appraisers are to be appointed under and in accordance with the terms of the contract of April 10, 1890, the said The Denver Union Water Company is unwilling to expend large sums of money in building pipes and conduit lines for use in the future and after the arrival of the time when the said City and County will have the right to purchase said plant under appraisement, in view of the existing uncertainty as to whether the City will exercise its right and option to purchase said plant at said time; and,

Whereas, as a result of said investigation, negotiations and inquiries made and conducted by the City and County of Denver, it has become apparent to said City that a delay in the appointment of said appraisers for more than two and one-half years, as provided by the terms of said contract, would be to the detriment of the City and County of Denver and its inhabitants, would produce an unsettled condition of affairs with reference to said purchase, causing financial loss to said corporation, and that it is desirable and will be of advantage to the City and County of Denver and the inhabitants thereof that there should be, as speedily as it may be had, an appraisement under said contract and a determination of whether the City will purchase the property owned and used by said The Denver Union Water Company in supplying water to the City and County of Denver and the inhabitants thereof; and,

Whereas, the City and County of Denver has obtained from said The Denver Union Water Company its consent to waive the period of time fixed and set forth in Section 11 of said contract and ordinance, and to agree to proceed in conjunction with the City and County of Denver in accordance with the terms of said contract to the appointment of said appraisers at the present time, and to permit the City and County of Denver to purchase said property upon an appraisement and in accordance with the terms and conditions of said contract and ordinance without awaiting the expiration of the period fixed therefor in and by the terms of said contract and ordinance; and,

Whereas, in connection therewith, the City and County of Denver has exacted and required of and from the said The Denver Union Water Company an agreement that the said The Denver Union Water Company will submit to the City Council of the City and County of Denver, and through it to the electors of the City and County of Denver, qualified to vote thereon, a proposition for a new contract, plainly specifying, setting forth and containing what rates for water furnished to private consumers shall be charged during said period and the rates and terms upon which it will supply to the City and County of Denver for its uses and for fire hydrant rentals

for said period of twenty years, within ninety days from and after the passage of this ordinance, said rates to be ascertained and fixed for said submission by the arbitrators selected to appraise the property of said company as hereinafter set forth; so that both of said propositions, to-wit:

1st. Shall the City and County of Denver purchase the property so owned and used by The Denver Union Water Company and such allied and auxiliary corporations, persons or associates as may hold the legal title thereto, now engaged in furnishing the City and County of Denver and its inhabitants with water at a price to be ascertained and fixed by said appraisers to be appointed in the manner provided for and with the qualifications set forth in said Section 11 of said ordinance?

2nd. Shall the people of Denver make a contract for a period of twenty years with rates for water to be furnished to the City and County of Denver, and to the private consumers of water therein, plainly, specifically and unmistakably set forth and ascertained by appraisers as hereinafter set forth? shall be submitted at the same election to the electors qualified to vote thereon.

So that the said electors of the City and County of Denver, so qualified to vote thereon, shall have the choice and opportunity of determining which of said propositions they may desire to accept; and the said City and County of Denver having also obtained from said The Denver Union Water Company the assurance and agreement that it will agree with the said the City and County of Denver to put in force an arrangement and agreement fixing temporary rates to be paid said The Denver Union Water Company by the private consumers of the City and County of Denver, to be charged and collected from and after the first day of November, A. D.
27 1907, and for the remainder of the term of the present contract, in the event that the City and County of Denver shall not, at said election hereinabove referred to, determine to purchase said plant or to extend or renew said contract for a further period of twenty years; and,

Whereas, it is the judgment of the Council of the City and County of Denver, under the circumstances above narrated, that it is advantageous to said City to proceed forthwith to an acceptance of said agreement of the said The Denver Union Water Company and to the appointment of appraisers as provided in Section 11 of said contract of April 10, 1890, and to accept the proposition of said The Denver Union Water Company to waive the time limit therein specified, and that in this determination and conclusion the City Council of the City and County of Denver is fortified by the fact that the contracts between The Denver Union Water Company and certain municipalities now incorporated in and made a part of the City and County of Denver require adjustment, the former town of Highlands and the former town of Globeville, now both embraced within the limits of the City and County of Denver;

Now, Therefore,

Be it Enacted by the Council of the City and County of Denver:

Section 1. In consideration of the premises and the mutual cov-

enants and agreements hereinafter set forth and in further consideration of Five ($5.00) Dollars in hand paid by the Denver Union Water Company to the City and County of Denver, the receipt whereof is hereby acknowledged and confessed, the City and County of Denver, party of the first part, and the said The Denver Union Water Company, a corporation organized and existing under the laws of the State of Colorado, party of the second part, hereby mutually covenant and agree to and with each other as follows, to-wit:

1. It is hereby agreed that five (5) disinterested persons, none of whom shall be residents of the City and County of Denver, shall be appointed to appraise the value of the plant and property of the said Company, two of them to be chosen by the City and County of Denver through a committee herein named and authorized to make such selection, two by The Denver Union Water Company, and the fifth by the four first chosen as herein provided, the said appraisers to be selected by the City and County of Denver, to be named by said committee composed of the Mayor of the said City and County of Dener, the President of the Board of Supervisors and the President of the Board of Aldermen of the City and County of Denver; and said Mayor, President of the Board of Supervisors and President of the Board of Aldermen are hereby authorized to make said appointments, and in the event that all three may not agree, then two thereof are hereby authorized and empowered to select such appraisers and to take such steps and legal action as may be necessary for that purpose; said selection or said appointment of said appraisers by The Denver Union Water Company and the City and County of Denver in the manner herein provided, to be made within thirty (30) days after the execution of this contract, and that the fifth of said appraisers shall be selected by the first four members selected as herein provided, within thirty (30) days after the appointment of said four appraisers.

2. It is further hereby agreed and provided that such appraisers and arbitrators, so selected as herein provided, after their selection and appointment and before proceeding to hear or determine the matters submitted to them, shall take and subscribe an oath before some person duly authorized by law to administer oaths, to the effect severally that they will well, truly and impartially discharge their duty as such appraisers and arbitrators and all the matters and things submitted to them under this agreement to the best of their ability.

3. It is further hereby agreed and provided that the decision of any three of said appraisers shall be binding as to the questions submitted to them for determination under this agreement.

4. It is further hereby agreed that said appraisers and arbitrators shall view the premises and examine the property affected by and to be appraised under this agreement and shall hear such evidence and make such inquiries with reference thereto as may enable them properly to understand their duty, and after having so done and having heard such matters as shall be brought to their attention by the parties hereto, respectfully, and such other evidence as

they may determine to consider affecting the value of the premises and property belonging to or used by The Denver Union Water Company, or any of its allied and auxiliary corporations or associations or persons connected with it, engaged in or assisting in the business of supplying the City and County of Denver and its inhabitants with water, and after hearing arguments by the respective representatives of the parties hereto, relating thereto and after due consideration of the same, shall determine and fix the fair cash value of the property, business and rights so owned or used by The Denver Union Water Company, party of the second part, its allied and auxiliary corporations and associations and persons connected with it aforesaid, by which said company at the present time supplies water to the said City and County of Denver, party of the first part, and its inhabitants, or to anyone else at any place whatever, for domestic, manufacturing, or irrigating purposes and which shall constitute and include all the property, rights and privileges of every kind and nature whatsoever acquired by said party of the second part from its predecessor, The Denver Water Company, or from any person or corporation whatsoever, whether the legal title be held by said The Denver Union Water Company or by some other person; and also all property, real or personal, easements, rights and privileges and contracts of every and all nature and kind whatsoever acquired by said party of the second part, its allied and auxiliary corporations or associations or persons connected with it, since their respective incorporations, which are in any way connected with or relate to said water plant of said The Denver Union Water Company, or held by its allied or auxiliary corporations or associations or persons connected with it, or necessary or useful for its protection, maintenance and operation; and also separately ascertain the fair cash value of all that portion of said pipes, pumps, hydrants, mains and valves now used by The Denver Union Water Company, party of the second part, its allied and auxiliary corporations or associations and persons connected with it, owned by the City and County of Denver, party of the first part.

5. It is further hereby agreed that upon the appointment of said appraisers and arbitrators as so provided, they shall with all convenient speed and dispatch proceed to the hearing and determination of the matters set forth in Section 4 hereof, and shall thereupon make a full and complete report of their determination in writing, signed by said appraisers, or in the event their determinations are not unanimous, by a majority thereof, one copy to be submitted to the Mayor and Council of the City and County of Denver, party of the first part, and one copy to The Denver Union Water Company, party of the second part; and thereafter and as soon as may be by proper procedure in accordance with law, there shall be submitted to the electors of the City and County of Denver to vote thereon, the question of whether the City and County of Denver shall purchase of The Denver Union Water Company, its allied and auxiliary corporations and associations and persons connected with it, their successors or assigns, the property referred to and described in Section 4 hereof, at and for the price fixed by said Board of Ap-

praisers and Arbitrators proceeding as aforesaid, and also at the same time, to the electors qualified to vote thereon, the question as to whether a contract or franchise shall be granted to The Denver Union Water Company, party of the second part, its successors and assigns, to supply water to the City and County of Denver and its inhabitants upon the schedule, terms and conditions and for the rates set forth in a proposition to be made by the said The Denver Union Water Company, party of the second part, as provided herein, with rates in said contract to be definitely fixed and easily and plainly understood, and to be ascertained and fixed by said Arbitrators herein provided for, and which shall be fair, just and reasonable rates for the water supplied and services performed and give to said Company fair, just and reasonable returns upon a fair and reasonable valuation of its property, and to cover a period of twenty (20) years from and after the date of said election; and it is further distinctly understood and agreed that The Denver Union Water Company, in said proposal for a new contract for said period of twenty (20) years, agrees to provide for the purchase for cash from the City and County of Denver of all the mains, pipes, pumps, hydrants and valves now used by the said The Denver Union Water Company, its allied or auxiliary corporations or associations, in furnishing the City and County of Denver, or its inhabitants with water, and which is now owned by said City and County of Denver, at and for the price to be fixed thereon by the appraisers and arbitrators herein provided for and who are to appraise and determine the value of said property for said purpose.

6. It is hereby further agreed that if at such election so to be held as herein provided, the electors qualified to vote thereon shall refuse to accept the proposition of the said party of the first part for a new contract with rates therein specified as herein provided, and the qualified electors to vote thereon shall accept the said proposition with reference to the purchase of said plant and property at the valuation fixed by said appraisers and arbitrators as herein provided, then the said The Denver Union Water Company, party of the second part, hereby convenants and agrees that it will upon the payment of the price so fixed by said appraisers, either in money or in the bonds of the City and County of Denver lawfully issued therefor bearing interest at the rate of four (4 per cent) per cent. per annum, convey, transfer and deliver to said City and County of Denver all of its said water plant and property, real and personal, with all the easements, rights and privileges, and all the property, real or personal, easements, rights and privileges of whatever kind or nature, belonging to its allied and auxiliary corporations and associations or persons connected with it, used in connection with the business of supplying water to the City and County of Denver and its inhabitants, and being the said property referred to in Section 4 hereof; and that from and after said transfer and the payment and delivery thereof to The Denver Union Water Company of said price therefor in cash or in said bonds of the City and County of Denver, as herein provided, all franchises, rights and privileges which have at any time theretofore been granted to the said The

Denver Union Water Company or its successors and assigns by the City and County of Denver, or any of its component municipalities, or which have been transferred to said The Denver Union Water Company, or to any of its successors and assigns, and its allied and auxiliary corporations or associations, and which it shall then possess, shall then be at an end without further action or determination of the same.

7. It is further hereby agreed that if at said election so to be held as herein provided, the electors qualified to vote upon said proposition shall refuse by their majority vote to accept the proposition of said The Denver Union Water Company and its allied and auxiliary corporations or associations, to purchase said water plant, but shall vote to grant a new contract to The Denver Union Water Company, specifying the rates therein to be charged in the manner herein provided, then said party of the second part, its successors and assigns, shall receive from the City and County of Denver a franchise or contract containing the terms provided for therein for a
28 period of twenty (20) years from the date of said election.

8. It is further hereby agreed that if at said election as herein provided, and which it is understood and agreed and is provided hereby shall be a special election called for considering said two propositions, the electors qualified to vote thereon shall, by their majority vote, refuse to accept either the proposition as to the purchase of said property or as to the granting of a new contract, the action of the said parties hereto in entering into this agreement and in submitting said matters to the vote of the electors qualified to vote thereon as herein provided, shall not constitute a waiver of the rights or privileges of either party hereto or prejudice in any manner or form or to any extent whatever the rights and privileges of the City and County of Denver, party of the first part, or The Denver Union Water Company, party of the second part, under and by virtue of the provisions, or any of them, of the said contract of April 10, 1890, being said Ordinance No. 44 of the Series of 1890, all the rights, privileges and franchises of either party hereunto provided for or contained in and by the terms of said contract and ordinance shall be and remain in full force and effect the same as if this contract and agreement had not been entered into and *and* said fifth appraiser so appointed for had been taken.

9. It is further hereby agreed that in case either of the parties named as appraisers and arbitrators by the party of the first part shall die, fail or refuse *to* become unable to act as such appraiser and arbitrator before the final determination of the matters herein involved, then the Mayor of the City and County of Denver is hereby authorized to forthwith thereafter name and appoint some other person, having the qualifications hereinbefore set forth, to be an appraiser and arbitrator in the stead and place of the one before appointed and unable and failing to act as herein provided; and so, in like manner, in case of either of the persons appointed as appraisers and arbitrators by the party of the second part shall die or refuse or become unable to act as such appraiser and arbitrator before the matters herein referred to are settled and the appraisement and arbi-

tration shall be determined, then the party of the second part is hereby authorized and empowered in the same manner as in the first instance to forthwith thereafter appoint some person, having the qualifications hereinbefore set forth, to act in the place and stead of the one theretofore appointed but being unable to act; and so, in like manner, in case the person appointed by the four other appraisers, as the fifth appraiser, shall die or refuse or fail or become unable to act as appraiser and arbitrator as herein provided, before all the matters referred to above are determined, then the four persons then acting as arbitrators and appraisers shall forthwith thereafter appoint a person having the qualifications aforesaid, as appraiser and arbitrator in the place and stead of the one theretofore appointed and whose death, failure or refusal to act has prevented him from participating in such appraisement, and said fifth appraiser so appointed shall have the same authority and power as was conferred upon the person theretofore appointed.

10. It is further hereby agreed that all costs and expenses incurred by reason of the appraisement, arbitration and special election hereby had and made under this agreement and under the terms and provisions of said contract, shall be borne by the parties hereto equally.

11. It is further hereby agreed that the parties hereto respectively shall produce before said appraisers and arbitrators while considering said matters, all books, deeds, papers, accounts, vouchers, writings and documents within their possession or under their control or under the control or in the possession of their allied corporations and associations or any person connected with them, which the said Board of Appraisers and Arbitrators may require, call for or request, bearing upon and properly relating to the matters submitted to said appraisers and arbitrators for consideration, and said appraisers and arbitrators may require and call for and request said matters and things from time to time as in their judgment they may deem desirable.

12. It is hereby further agreed that said appraisers and arbitrators shall be at liberty to and are hereby authorized and empowered to proceed, without the party or parties failing to attend before them, in case of the non-attendance of the parties to this agreement, or any of them, or any of the witnesses or representatives of the parties to this agreement, or any of them, or in case of the failure on the part of said parties, or either of them, to produce any books, deeds, papers, accounts, vouchers, writings, or other documents within their possession or under their control or under the control of their allied or auxiliary corporations or associations, or any person connected with them, which the said board of appraisers and arbitrators shall call for or request, after three (3) days previous notice in writing, under the hands of the members of said board given to the said parties or witnesses and their designated representatives notifying them to produce such books, deeds, vouchers, papers, accounts, writings or other documents, and of the time and place where the same are to be produced.

13. It is hereby agreed and provided that the said respective parties hereto shall each pay the appraisers named by them, and shall

share and pay equally the amount of the fifth appraiser as herein provided for.

It is hereby agreed that the said appraisers and arbitrators shall have the power if in their opinion it shall be necessary to employ an accountant to assist them, and that all other necessary aid and assistance required by said appraisers and arbitrators shall be furnished by and at the expense of the parties of the first and second parts hereto.

In Witness Whereof the party of the first part has caused these presents to be signed by its Mayor, attested by its Clerk, and its corporate seal to be hereunto affixed, and the party of the second part, being duly and legally authorized thereunto, has caused these presents to be signed by its President, attested by its Secretary, and its corporate seal to be hereunto affixed, this — day of ——, A. D. 1907.

Section 2. The Mayor of the City and County of Denver is hereby authorized, empowered and directed to subscribe said agreement herein adopted and hereinbefore set forth in Section one (1) hereof, and the City Clerk of the City and County of Denver is hereby authorized, empowered and directed to attest such act of said Mayor and to affix to said contract the seal of the City and County of Denver, and the Auditor of the City and County of Denver is hereby authorized, empowered and directed to countersign and register said contract.

Section 3. The Mayor of said City and County of Denver, the President of the Board of Supervisors and the President of the Board of Aldermen are hereby named, constituted and appointed a committee of three and are hereby authorized, empowered and directed to name and appoint the appraisers and arbitrators provided for in said agreement and set forth in Section one (1) hereof to be appointed and named by the said the City and County of Denver.

Section 4. The Denver Union Water Company within ten days after the passage and publication of this ordinance shall sign and subscribe said contract and agreement herein recited and adopted and set forth in Section one (1) hereof, and upon its failure so to do this ordinance and contract shall become null and void.

JOHN CONLON,
President of the Board of Aldermen.
A. J. SPENGEL,
President of the Board of Supervisors.

Signed and approved by me this 2nd day of October, A. D. 1907.
R. W. SPEER, *Mayor.*

Attested by the undersigned with the corporate seal of the City and County of Denver.

[SEAL.]
E. E. SOMERS,
Clerk of the City and County of Denver.

Published in The Denver Republican this 4th day of October, A. D. 1907.

29 STATE OF COLORADO,
City and County of Denver, ss:

I, Burt F. Davis, Clerk of the City and County of Denver and State aforesaid, do hereby certify that the foregoing is a full, true and correct copy of Ordinance No. 163, series 1907, of the city of Denver, the original of which is on file and of record in my office.

Witness my hand and the seal of said City this — day of August, A. D. 1910.

—— ——,
City Clerk,
By —— ——, *Deputy.*

In and by said ordinance it was contemplated and provided that a contract in form and substance as set forth therein should forthwith be entered into between complainant and defendant the city and county of Denver, to the effect that the city and county of Denver should be and was granted the privilege of causing the appraisement contemplated by Section 11 of Ordinance No. 44 of the Series of 1890 to be forthwith made prior to April 10th, 1910; and thereafter, and within ten days after the passage and publication of said Ordinance No. 163 of the Series of 1907, complainant and defendant the city and county of Denver did make and enter into the contract in form and substance as set forth in said Ordinance No. 163 of the Series of 1907, to the effect and as contemplated
30 and provided in said ordinance.

Shortly after the passage and approval of said ordinance No. 163 of the Series of 1907 and the execution and delivery, in pursuance thereof, of said contract, and in full compliance with the terms of both said ordinance and said contract, five appraisers or arbitrators were duly appointed. All of said appraisers or arbitrators were non-residents of the city and county of Denver, wholly disinterested and impartial, and in the highest degree qualified by training and experience to perform the duties imposed upon them in connection with said appraisement.

The appraisers selected by complainant were: John R. Freeman, of Providence, Rhode Island, and C. L. Harrison, of New York City. Prior to the selection of appraisers for defendant the city and county of Denver, the Mayor of said city submitted to the various commercial bodies of said city a list of names, stating to each of said commercial bodies that the city and county of Denver had practically decided to make its selection from among the men mentioned in said list, thereby presenting the matter to the public, and requesting that if any of said organizations or any citizen knew of any good reason why any of said parties should not be appointed as appraisers for said city and county of Denver the Mayor should be advised without delay. No objection was made to any of the persons named in said list, but on the contrary, all of them received the approval of
31 said commercial bodies. Upon the list so submitted appeared the names of Frederick P. Stearns, of Boston, Massachusetts, Allen Hazen, of New York City, and M. L. Holman, of St. Louis,

Missouri. Thereafter the defendant, the city and county of Denver, appointed said Frederick P. Stearns and said M. L. Holman as its appraisers, and thereafter the four appraisers so selected by the complainant and the defendant the city and county of Denver proceeded to and did select as the fifth appraiser, contemplated in and required by the provisions of said ordinance, Allen Hazen. Each of said appraisers was of national eminence and of the highest reputation and ability, an hydraulic and civil engineer of unquestioned integrity, and by experience, ability and training, particularly in reference to any matters relating to waterworks and the supplying of water to large cities, was in the highest degree qualified in every particular to perform the duties which he assumed.

After the appointment and de-signation of said appraisers they duly qualified, in conformity with said ordinance No. 163 of the Series of 1907; and thereupon said appraisers proceeded to make an appraisement of all of the property and plant constituting the water works system of complainant, including the property of The South Platte Canal and Reservoir Company, being the system and property used and necessary to be used in supplying the defendant
32 the city and county of Denver and its inhabitants thereof with water for all purposes, and being included in the property and water system of complainant now being used in supplying the city and county of Denver and its inhabitants with water, and being the same property and system now used, except for the additions, extensions, betterments and improvements which complainant has made to its water system since the date of said appraisement, and as hereinafter more specifically set forth. Full hearings were had before said Board of Appraisers, evidence taken and arguments presented for and on behalf of both parties, towit, complainant and defendant the city and county of Denver. Personal examinations and investigations were made by said Board of Appraisers, and after the most careful, thorough, complete and impartial investigation and hearings by them covering a period of about eighteen months, and after allowing both complainant and its representatives, and the defendant the city and county of Denver and its representatives, the fullest opportunity to present any and all evidence and to be heard in respect to every point involved, the Board of Appraisers did on March 20th, 1909, find and determine and announce its findings and determination to the effect that the value of said property so devoted to the supplying and necessary to the supplying of the city and county of Denver and its inhabitants with water, as of the date of said appraisement, was the
33 sum of fourteen million, four hundred thousand dollars ($14,400,000.00), which said amount said Board of Appraisers announced should be subject to an equitable adjustment between the parties as of the date of any actual purchase and relating to changes, if any, which might have occurred since the date to which said appraisement referred, particularly in respect to the stock of material on hand, including the personal property not directly connected with the system, and which the said Appraisers announced could readily be done; and also subject to any additions and bet-

terments to the plant which might be made subject to the date of said appraisement.

A copy of said Appraiser's Report is as follows:

34 *Report of The Board of Appraisers and Arbitrators Upon the Property of The Denver Union Water Co. March* 20, 1909.

35 Report of The Board of Appraisers and Arbitrators Upon the Property of The Denver Union Water Company March 20, 1909.

36 Report of the Board of Appraisers and Arbitrators Constituted by the Terms of a Certain Agreement Between the City and County of Denver and The Denver Union Company, Dated the Tenth Day of October, A. D. 1907.

To the Honorable the Mayor and City Council of the City and County of Denver, and to The Denver Union Water Company.

The undersigned, having been duly selected and appointed as members of the Board of Appraisers and Arbitrators under and pursuant to the terms of a certain agreement between the City of Denver and The Denver Union Water Company, dated the 10th day of October, A. D. 1907, and authorized on the part of the City and County of Denver by Ordinance No. 163 of the Series of 1907, to which reference is hereby made, report as follows:

That having been each separately duly qualified pursuant to the provisions of paragraph 2, section 1 of Ordinance No. 163, of the Series of 1907, and having taken and subscribed an oath as in said paragraph prescribed, before the Honorable The Chief Justice of the Supreme Court of the State of Colorado; and,

Having, pursuant to the provisions of paragraph 4, section 1, of Ordinance No. 163, of the Series of 1907, viewed the premises and examined the property affected by and to be appraised under said agreement, and heard such evidence and made such inquiries with reference thereto as might enable us properly to understand our duty, and having so done, and having heard such matters as were brought to our attention by the parties to said contract respectively, and such other evidence as we determined to consider, affecting the value of the premises and property belonging to or used by The Denver Union Water Company, or any of its allied or auxiliary corporations or associations or persons connected with it, engaged in or assisting in the business of supplying the City and County of Denver and its inhabitants with water, and having heard arguments by the respective representatives of the parties to said contract relating thereto, and having given due consideration to the same:

First. We hereby determine and fix the fair cash value of the property, business and rights owned or used by The Denver
37 Union Water Company, party of the second part, its allied and auxiliary corporations and associations and persons con-

nected with it aforesaid, by which said company at the present time supplies water to the said City and County of Denver and its inhabitants, or to any one else, at any place whatever, for domestic, manufacturing or irrigating purposes, and which constitute and include all the property, rights and privileges of every kind and nature whatsoever acquired by The Denver Union Water Company, from its predecessor, The Denver Water Company; of from any person or corporation whatsoever, whether the legal title be held by The Denver Union Water Company or by some other person; and also all property, real or personal, easements, rights and privileges and contracts of every and all nature and kind whatsoever acquired by The Denver Union Water Company, its allied and auxiliary corporations or associations or persons connected with it since their respective incorporations, which are in any way connected with or related to the water plant of The Denver Union Water Company, or held by its allied or auxiliary corporations or associations or persons connected with it, or necessary or useful for its protection, maintenance and operation, at the sum of fourteen million, four hundred thousand dollars ($14,400,000.00).

For the information of the parties hereto, it may be stated that the total sum of $14,400,000.00 so determined and fixed as the fair cash value of the property, business, etc., above described, may be divided and distributed in the following manner:

(*a*) The physical plant, including all land and all structures, based on the fair cash value of the land and the fair and reasonable cost of reproducing the structures, including allowances for interest during construction, engineering, contingencies and general expenses, and with due deductions for the depreciation because of wear and tear, and allowances for increase or decrease in utility and value for the purposes for which they are used, the sum of ten million, three hundred fifty-four thousand, seventy five dollars ($10,354,075.00).

(*b*) Water rights owned or used by The Denver Union Water Company, the sum of two million, eight hundred forty-five thousand, nine hundred twenty-five dollars ($2,845,925.00).

(*c*) Business and going concern value, representing the added value of the plant because of its connections and business, and because the parts are united into one system and are tested and in successful use, and the value of the business during the remainder of the present franchise term, one million, two hundred thousand dollars ($1,200,000.00).

For the further information of the parties hereto, we append a schedule of the items of physical property that we have considered, including joint reports upon certain quantities and certain values that we have considered in making our award.

We further call attention to the fact that this appraisal is made and the value so fixed and determined has been arrived at, upon
38 the data and the schedules furnished to the board during its session, and the changes, if any, which have occurred in these schedules, particularly having reference to the stock of material on hand, including personal property not directly connected with the system, and including pipes, valves, wood staves, bands, cement,

shall be subject to equitable adjustment between the parties as of the date of the actual purchase, if made, and this can quite readily be done.

Second. We hereby separately ascertain, determine and fix the fair cash value of all of that portion of said mains, pipes, pumps, hydrants and valves now used by The Denver Union Water Company, its allied and auxiliary corporations or associations and persons connected with it, and owned by the City and County of Denver, at the sum of three hundred fifteen thousand dollars ($315,000.00).

A copy of this report is submitted and sent to the Mayor and City Council of the City and County of Denver, and likewise to The Denver Union Water Company; and such further reports, pursuant to the terms of said contract between the parties, and said Ordinance No. 163, of the Series of 1907, will hereafter be made as are required.

All of which is respectfully presented this, the twentieth day of March, A. D. 1909.

(Signed) M. L. HOLMAN.
JOHN R. FREEMAN
C. L. HARRISON.
ALLEN HAZEN.

I assent to all parts of the foregoing report except the valuation given therein of the water rights owned or used by The Denver Union Water Company.

(Signed) FREDERIC P. STEARNS.

List of Water Rights of The Denver Union Water Company.

The South Platte River in Water District No. 8.

1. 34.00 cubic feet per second, Platte Canon Ditch. Appropriation and decree as of December 30, 1863.

17.30 cubic feet per second, Platte Canon Ditch. Appropriation and decree as of December 30, 1864.

Both appropriations changed from an irrigation use to an all-the-year domestic use and city supply in 1889. Subject to the right of other parties to irrigate 195 acres of land. Prior appropriations out of the Platte River, 58 cubic feet per second. Total decreed appropriations from the Platte River and tributaries in Water District No. 8, 2,848 cubic feet per second.

2. 37.00 cubic feet per second, Rough and Ready Ditch and Mill Race. Appropriations as of December 31, 1860.

31.27 cubic feet per second, same December 31, 1867.

Appropriations for power purposes purchased by the Water Company to protect its Platte Canon Ditch rights.

3. 1.00 cubic foot per second in the Northern Colorado Irrigation Company's ditch, which has an appropriation of 1,184 cubic feet, as of January 18, 1879. Purchased with the land embraced in the Platte Canon Reservoir, owned by the company, and giving a claim of right for headgate in said ditch for water for said reservoir.

4. Contracts with the Northern Colorado Irrigation Company for carrying water belonging to the company—Platte Canon Ditch rights and Cheesman Lake water, and 34-inch conduit appropriation—from headgate and dam of said Northern Colorado Irrigation Company's canal to said Platte Canon reservoir.

5. 2.50 cubic feet per second for all domestic and municipal purposes. Appropriation as of December 20, 1870, by the erection of pumping plant and waterworks in the city of Denver.

6. 24.00 cubic feet per second for all domestic purposes and 6.00 cubic feet per second for municipal and all beneficial purposes other than irrigation by the erection of the pumping plant in West Denver and the Mississippi filtering beds September 10, 1878, but relating back to December 20, 1870.

41 7. 11.44 cubic feet of water per second for all domestic purposes, and 2.76 cubic feet of water per second for municipal and all other beneficial purposes other than irrigation by the construction of the 30-inch conduit or pipe line diverting water through galleries in the bed of Cherry Creek (a tributary to the South Platte River) in the northwest quarter of section 28, township 4 south, range 67 west, constructed in the spring of 1889, but relating back to December 20, 1870.

8. 9.90 cubic feet of water per second for all domestic purposes, and 2.48 cubic feet of water per second for municipal and all other beneficial purposes other than irrigation by the construction of the 30-inch conduit or pipe line diverting the underflow and surface water through galleries in the west bank of the South Platte River in the north-east quarter of section 34, township 6 south, range 67 west, in the spring of 1889, but relating back to December 20, 1870.

9. 19.80 cubic feet of water per second for all domestic purposes, and 4.95 cubic feet of water per second for municipal and all other beneficial purposes other than irrigation by the construction of the 34-inch conduit or pipe line diverting water through a headgate situate in the east bank of the South Platte River, in the northwest quarter of the northeast quarter of section 5, township 7 south, range 69 west, in the year 1892, but relating back to December 20, 1870.

10. 30.34 cubic feet of water per second for all domestic purposes, and 7.74 cubic feet of water per second for municipal and all other beneficial purposes other than irrigation by the construction of the 40-inch conduit or pipe line diverting water through headgates in the west bank of the South Platte River in the southwest quarter of section 34, township 6 south, range 69 west, in May, 1899, but relating back to December 20, 1870.

11. 278.26 cubic feet of water per second, appropriation of the Denver City Irrigation and Water Company, as of September 10, 1878, for power purposes West Denver pumping plant, Archer Lake.

12. Lake Cheesman Dam and Reservoir—Appropriation of all the unappropriated and flood waters and winter flow of the South Fork of the South Platte River above said dam for the full capacity of said reservoir and to refill the same at all times whenever and as fast as water is withdrawn or used from said reservoir for any purposes. Appropriation dating from December 28, 1889, and October 23, 1893.

Surface area of reservoir, 874.08 acres.

Capacity, 3,444,038,412 cubic feet, or 25,761,407,322 gallons above the lower tunnel.

Lake Cheesman is in Water District No. 23.

13. Bear Creek, Water District No. 9—100 shares in The Harriman Ditch Company, out of a total of 400 shares.

42 The Harriman Ditch Company is the successor of The Arnett Ditch Company and owns all of the latter's appropriations of water, viz.:

March 16, 1869	7.94 cubic feet.
May 1, 1873	25.54 cubic feet.
March 1, 1882	12.87 cubic feet.

14. 60 shares in The Soda Lakes Reservoir out of a total of 400 shares. Appropriation from Bear Creek through The Harriman Ditch Company of 120,252,689 cubic feet as of May 4, 1893.

15. 72 shares of The Bergen Ditch Company out of a total of 400 shares. Appropriation of May 1, 1874, of 12.00 cubic feet. Turkey Creek.

16. Marston Lake Reservoir—Capacity, 862,257,600 cubic feet, or 6,449,686,848 gallons. Filled and supplied by the Harriman ditch, through the above rights owned by the company in said ditch and in Soda Lakes, and by means of items Nos. 17 and 18, following:

17. Appropriation made by The Harriman Ditch Company September 21, 1892, of all the unappropriated and flood waters and winter flow of Bear Creek to fill and supply 19 reservoirs under said ditch, including Marston Lake. After this appropriation was made the ditch was greatly enlarged for the purpose of carrying this appropriation.

The ditch was enlarged at that time to a carrying capacity of 150 cubic feet per second.

18. Contract with The Harriman Ditch Company for all the surplus water carried by said ditch to fill Marston Lake.

NOTE.—The Water Company owns 100 shares of the stock of this company, as shown above, out of a total of 400 shares, and has perpetual proxies for 110 shares, in addition, making 210 under its control, so that it has absolute control of the ditch.

19. Harriman Lake—Capacity, 38,072,839 cubic feet. Reservoir Appropriation No. 1, in Water District No. 9, May 1, 1873, 18.00 cubic feet per second.

20. Water bearing lands and subterranean water. See list of real estate.

Messrs. Allen Hazen, John R. Freeman, C. L. Harrison, F. P. Stearns, M. L. Holman, Appraisers of The Denver Union Water Company's Plant and Property.

GENTLEMEN: In the list heretofore handed to you of the water rights owned by The Denver Union Water Company, the following were inadvertently omitted, to wit:

43 1. Appropriation belonging to The Harriman Ditch Company, made by its predecessor, The Arnett Ditch Company, from Turkey Creek, in Water District No. 9, being Priority No. 21, of date April 15, 1868, for 10.75 cubic feet of water per second.

2. Water right from The Northern Colorado Irrigation Company's canal for 20.64 acres to irrigate land owned by The Denver Union Water Company in the south half of the south-east quarter and the south half of the south-west quarter of section 28, township 4 south, range 67 west.

Respectfully submitted,

(Signed) W. P. MILLER, *Secretary.*

Denver, Colorado, December 17, 1907.

44 *Report of the Value of Real Estate Owned by the Denver Union Water Company in the City of Denver.*

DENVER, COLORADO, December 10, 1907.

To the Honorable Board of Appraisers:

GENTLEMEN: The undersigned, appointed respectively by the City and County of Denver and The Denver Union Water Company, at your request and under your authority, to estimate and appraise the present value of all the lands and real estate owned by said The Denver Union Water Company, situate in the City and County of Deuver, as well as certain tracts of land in Jefferson County and two separate tracts, together with the improvements thereon, situate in the Town of Littleton, Arapahoe County, Colorado, beg leave to report that, after careful examination of the several tracts and an investigation of such matters as would aid in arriving at a conservative valuation of the properties in question, the following stated values have been jointly agreed upon and fixed by us as the reasonable and fair value of the properties hereinafter described, viz.:

All of block 7, Weir Addition, on South Zuni street, between West Seventh and West Sixth avenues, on the line of The Denver, Marshall & Boulder Railroad, comprising 26 fractional lots, suitable for trackage purposes.	$1,200.00
Plats 2, 7 and 8, block 38, Eastern Capitol Hill Sub-division on Second avenue between Cherry street and Clermont street, comprising 12 regular size city lots, including 2 corners	1,350.00
NOTE.—There is an artesian well cased to a depth of 700 or 800 feet on these lots, the value of which has not been taken into consideration.	
Lots 11 and 12, block 48, Second Filing of a portion of Highland Park, on West Thirty-fifth avenue, between Boulevard F and Grove street	800.00
All of block 19, Cottage Hill, 38 lots, 4 corners; lots 1 to 32, block 20, Cottage Hill, 33 lots; lots 1 to 10, block 23, Cottage Hill, 10 lots; lots 1 to 12, block 22, Cottage Hill, 12 lots; comprising 93 lots, located on	
45 West Thirty-third and West Thirty-fourth avenues, Moncrieff place, Yates street and Sheridan boulevard	15,850.00
NOTE.—The Cottage Hill Tank of the Water Company is located on a portion of block 22, the value of which has not been appraised.	
Lots 1, 2, 3 and north 5 feet of lot 4, block 10, De Lappe place, located at the corner of West Twenty-ninth avenue and Sheridan boulevard	375.00

Lots 23 to 26, block 50, University Park, amended map, 4 lots, corner of Iliff avenue and South Harrison street			300.00
NOTE.—This is the location of the University Park Tank, the value of which has not been appraised.			
Lot 19, block 33, Witter's First Addition. This lot is located in West Eleventh avenue at the intersection of South Thirteenth street			1,000.00
Lots 4 and 19, block 6; lot 4, block 7, Titus Addition; west half of south half of south-east quarter of north-west quarter of section 4, township 4 south, range 68 west, except 50 feet off of west end of said tract conveyed to The Denver, South Park and Pacific Railway Company ...	9.25	acres	
Part of the south-east quarter of the north-west quarter, section 4, township 4 south, range 68 west	1.00	acre	
Part of the south-east quarter of the north-west quarter of section 4, township 4 south, range 68 west..	0.21	acre	43,200.00
NOTE.—The above mentioned four tracts, containing 10.80 acres, are the lands upon which are located the West Denver pumping station, reservoirs, storehouses, stables, etc., the value of some of which said improvements is included herein.			
Part of the south-east quarter of the north-east quarter, section 5, and part of the south-west quarter of the north-west quarter, section 4, township 4 south, range 68 west.....	2.85	acres	
Part of the south-west quarter of the north-west quarter, section 4, township 4 south, range 68 west	0.64	acre	
46 Part of the south-west quarter of the north-west quarter, section 4, township 4 south, range 68 west	1.90	acres	10,780.00
NOTE.—The above described 5.39 acres is land occupied by the tail-race from the West Denver pumping station.			
Part of the north-east quarter of the south-west quarter, section 4, township 4 south, range 68 west	4.03	acres	

Part of the south-west quarter of the south-east quarter, section 4, township 4 south, range 68 west	0.88	acre
Part of the south-east quarter of the south-west quarter, section 4, and of the north-east quarter of the north-west quarter, section 9, township 4 south, range 68 west	17.31	acres
Lots 1 to 5, block 1; lots 1 to 5, block 2; lots 32 to 37, block 2, Middaugh's Addition to Denver; strip of land off of the east or rear end of lots 6 to 11, block 1, and lots 1 to 20, block 8, Middaugh's Addition	1.01	acres
Part of north-east quarter of north-west quarter, section 9, township 4 south, range 68 west.....	2.00	acres
Part of west half of north-east quarter and of south-east quarter of north-west quarter, section 9, township 4 south, range 68 west	20.97	acres
Part of south-west quarter of north-east quarter, and of south-east quarter of north-west quarter, section 9, township 4 south, range 68 west..	10.20	acres
Part of north half of south-east quarter of section 9, township 4 south, range 68 west	8.34	acres
Part of south-east quarter of south-east quarter, section 9, township 4 south, range 68 west.....	5.00	acres
Part of south-east quarter of south-east quarter of section 9, township 4 south, range 68 west, except 50 feet by 100 feet in south-west corner..	8.00	acres
Part of south-east quarter of south-east quarter, section 9, and of north-west quarter of north-west quarter, section 15, and of north-east quarter of north-east quarter, section 16, township 4 south, range 68 west	16.447	acres
47 East half of south-east quarter of north-east quarter, section 16, township 4 south, range 68 west	20.00	acres
Part of west half of south-west quarter of section 15, township 4 south, range 68 west	6.06	acres

Part of north-west quarter of north-west quarter, section 22, township 4 south, range 68 west	13.31	acres	
	131.557	acres	$174,334.50

NOTE.—The above described 14 tracts of land comprises what is known as the Lake Archer Canal and Mississippi Street Galleries, and along and through which tract is laid the West Denver conduit, and the value thereof is estimated as being restored to its natural condition.

Part of south-west quarter of south-east quarter, section 11, township 4 south, range 68 west.....	5	acres	10,000.00
Alameda Avenue Tank—			
NOTE.—Improvements have not been appraised.			
Part of north-west quarter of south-east quarter, section 25, township 3 south, range 69 west	8.37	acres	7,533.00
Ashland Avenue Reservoir Site—			
NOTE.—Value of improvements has not been appraised.			
Lots 1 to 11, block 1, Resubdivision of Lakeside, Jefferson County, Colo..			1,375.00
Ashland Avenue Pump Station Site—			
NOTE.—Improvements have not been appraised.			
Lots 11 to 20, block 5; lots 28 to 40, block 6, Chamberlin's Capitol Heights			250.00
NOTE.—These lots adjoin the Capitol Hill Reservoir on the east.			
Lots 25 to 44, block 3, Littleton Heights; improvements, $5,500; real estate $4,000			9,500.00
NOTE.—This is the residence and office of the superintendent and headquarters of the river division of the water system.			
48 North-west quarter of south-west quarter of north-east quarter, section 20, township 5 south, range 68 west.....	10.00	acres	

Tract of land in section 17, township 5 south, range 68 west; improvements, $15,500; real estate, $15,200	3.50	acres	28,700.00
NOTE.—These two tracts are occupied by the mill warehouses, dam and power ditch of The Littleton Milling and Water Power Company. The value of the water power in connection with this property has not been appraised.			
Lease of the premises at 1654 Broadway, occupied by the offices of The Denver Union Water Company, expiring November 1, 1913.....			$12,000.00
Lease of the premises in rear of 1640 Broadway, occupied as a garage of The Denver Union Water Company, expiring November 19, 1908			No value
Total			$318,547.50

Lease of the north-east quarter of north-west quarter of section 1, township 4 south, range 68 west, dated February 25, 1887. Terms: "From the date hereof, so long as the said party of the second part, its successors or assigns shall furnish and supply the City of Denver, and the inhabitants thereof, with water," etc. Rental, $500.00 per annum.

Lease of a strip of land 50 feet wide along the north side of the south-east quarter of North-west quarter of south-west quarter, section 1, township 4 south, range 68 west, dated March 25, 1903. Terms: "From the day of the date hereof for during and until the first day of January, A. D. 1923." Rental, $75.00 per year.

NOTE.—The two leases last mentioned are for tracts of land, the value of which is estimated at $35,000.00, owned by the City and County of Denver, and used for the Capitol Hill Reservoir and Pumping Station. These leases are a valuable asset of the Water Company, but in view of the fact that this appraisement is being made for the purpose of a sale to the city from which the leases were obtained, we are at a loss to determine their value, and think it best to leave the matter to your board. In the event that the Water Company's properties were being sold to another corporation, or to individuals, these leases, the principal one being practically perpetual,
49 and the other for a long term, would unquestionably be of great value.

Respectfully submitted,

(Signed) VICTOR R. OLMSTED,
WM. W. WATSON.

50 *Report on the Value of Real Estate Owned by the Denver Union Water Company Outside of the City Limits.*

To the Honorable R. W. Speer, Mayor of the City of Denver, and to The Denver Union Water Company of Denver, Colorado:

GENTLEMEN: We, the undersigned, J. B. McNeil, of 512-20 Cooper Building, Denver, Colorado, appointed by the Honorable R. W. Spear, Mayor of Denver, and Burton D. Sanborn, of Greeley, Colorado, appointed by The Denver Union Water Company, as appraisers to appraise the lands of The Denver Union Water Company lying outside of the City of Denver, both with and without water rights, do hereby respectfully report that we have not considered in this report the particular water rights which The Denver Union Water Company own, it being our understanding that they own in the aggregate more than sufficient water to fully irrigate all the lands reported by us as irrigable, on which we have placed a value of water rights, and on account of the amount of water which we understand said company own, and the large amount of storage capacity under their control, we have seen fit to describe said water rights to go with irrigated lands in acre feet, and following in this report wherever we appraise land with water unless otherwise specified, we consider one and three-fourths (1¾) acre feet a full and ample supply for each acre of land, and our only concern has been that land described with water right is located under some good ditch and capable of being irrigated from some of the supplies of the Water Company by means of existing structures, or ditches, and that the lands not so situated as to be under the present possibility of irrigation from existing ditches are classed by us as pasture lands and no water is apportioned to same, together with river bottom land, which is not suitable for cultivation.

We wish it to be understood that we have not given attention to the value of any of these lands for dry farming, and if they are valuable for such purposes, we are not appraising said value.

With the foregoing explanation we hereby respectfully submit the following valuations of lands and water rights described herein, and certify that in our judgment the value placed thereon are the fair cash values of said properties.

For convenience, the value of lands and water will be tabulated in column one; the value of lands without water, in column two; and the value of buildings, in column three:

	No. 1.	No. 2.	No. 3.
South-east quarter of south-west quarter, south half of south-west quarter of south-west quarter, section 33, township 6 south. North-west quarter of south-west quarter of north-west quarter, section 4. South-east quarter of north-east quarter, section 5, township 7 south, range 69 west. Lot No. 16444, embracing a portion of said sections 4 and 5, 152,624 acres.....	.....	$765.00	.....
These lands are not irrigable and are only valuable for pasture, except that they lay on both sides of the Platte river and on the Colorado & Southern Railroad in the Platte Canon.			
North-east quarter of south-east quarter, section 33, west half of north-east quarter, section 34, east half of north-west quarter, section 34, south-west quarter of north-west quarter, section 34, north half of south-west quarter, section 34. All in township 6 south, range 69 west, except 13.35 acres conveyed to The Denver, Leadville & Gunnison Railway Co. 306.65 acres.			
Most of these lands are too rough to be of any value for farming purposes, and make very poor pasture. They lay on both sides of the South Platte River and the Colorado & Southern Railroad. At the northern end the valley widens out sufficient to allow of a mill site, and some of this land has some value for this purpose.			
Average value, $9.00 per acre.....	.....	2,760.00	.....
Part of north-west quarter, section 35, township 6 south, range 69 west; part of north-west quarter, section 35, township 6 south, range 69 west; part of north-west quarter of north-west quarter of north-east quarter, section 35, township 6 south, range 69 west.			
Total acreage, 112.97 acres.			
52 We understand that the Platte Canon Reservoir, which is in part of the above land, is much more valuable as an			

THIS PAGE BOUND

irrigation reservoir than for agricultural purposes, and we do not appraise the same. The remaining portion of the land, amounting in all to 54.7 acres, is worth $15.00 an acre.....	.....	820.00	.....
We understand that there is one cubic foot of water in the High Line Ditch, which we do not appraise.			
Part of north-east quarter of north-east quarter, section 34, township 6 south, range 69 west, 3.22 acres.			
This land has been improved for filter beds and is worth much more for such purposes than any other; to destroy said filter beds and use for other purposes, our value is.....	.....	300.00	.....
Part of the south-east quarter of north-east quarter, section 34, township 6 south, range 69 west, 10.06 acres.....	.....	.....	.....
This land is also used as filter beds, but if not used for such purposes our value is.....	.....	700.00	.....
Part of the north-east quarter of the north-east quarter, section 34, township 6 south, range 69 west, except 3.22 acres above described, 22.99 acres	.....	.....	.....
This land is improved with buildings, used by water system, which buildings are not appraised by us.			
16 acres of land with water.....	$1,600.00	560.00	.....
7 acres	.....	70.00	.....
Part of the south-east quarter of the north-east quarter, section 34, township 6 south, range 69 west, 10.3 acres.			
The river runs through this land, which is not valuable enough to put water with it.....	.....	103.00	.....

53 Platte Canon Lands.	No. 1.	No. 2.	No. 3.

Lehow Lake—Part of the south-west quarter of south-west quarter, section 26, township 6 south, range 69 west, 13.08 acres.

This land is also more valuable for water works than for any other purpose, but if its use is discontinued for such purpose, it would still be valuable for fishing and ice in winter.....	.....	500.00	.....
Platte Valley Ranches.			
Phebe Strong Ranch—North half of north-east quarter, north half of north-west quarter, south-east quarter of north-east quarter, north half of south-east quarter, north-east quarter of south-west quarter, section 22, township 6 south, range 69 west, 320 acres at $5.00 per acre.....	.....	$1,600.00	.....
All of south-west quarter, section 23, township 6 south, range 69 west, and all that part of the north-east quarter, section 26, township 6 south, range 69 west, 200 acres, 126 acres choice land.....	$17,640.00	9,450.00	.....
68 acres dry pasture.....	.....	.....	.....
6 acres river pasture.....	.....	740.00	.....
Buildings are on the south-west quarter of south-west quarter, in all	.....	.....	1,500.00
South-west quarter of north-west quarter, south-east quarter of north-west quarter, south-west quarter of north-west quarter, north-west quarter of south-west quarter, all in section 22, township 6 south, range 69 west, 160 acres at $6.00 an acre.....	.....	960.00	.....
This land is fenced and has water for stock.			
William Strong Ranch and Canon Filter Plant—South-west quarter of south-west quarter, section 14; west half of north-east quarter, section 23; all of north-west quarter, section 23; all in township 6 south, range 69 west, 280 acres. 145 acres of choice land	20,300.00	10,875.00	.....
75 acres upland pasture.....	.....	750.00	.....
60 acres of river bottom, gravelly, appraised as pasture.....	.....	600.00	.....

Value of buildings	.....	.....	500.00
Becky Archer Ranch—North half of south-west quarter, south-east quarter of south-west quarter, south-west quarter of south-east quarter, section 14, all in township 6 south, range 69 west, 160 acres. 130 acres of choice farm land at $140.00 per acre	18.200.00	9.750.00	.....
20 acres dry pasture	.....	200.00	.....
10 acres river pasture	.....	100.00	.....
Value of buildings	.....	.....	1,000.00
Frank Archer Ranch—South half of south half, section 11; all of the north-west quarter, section 14; west half of north-east quarter, section 14; north-west quarter of south-west quarter, section 14; south half of south half, section 15; all in township 6 south, range 69 west, 600 acres, 300 acres choice land	42,000.00	22,500.00	.....
65 acres dry land	.....	650.00	.....
35 acres timber and bottom land, $20.00 an acre	.....	700.00	.....
Buildings on this place are very large and expensive, valuation	.....	.....	8,000.00
Mountain Reservoir Site—South half of section 16; all of south-east quarter of section 17; east half of east half of south-east quarter of north-east quarter, section 17; all of the north half of section 21; all in township 6 south, range 69 west, 810 acres. This land, in our judgment, is only suitable for dry pasture, is fenced and has stock water, $6.00 an acre	.....	4,860.00	.....

55 Platte Valley Ranches.	No. 1.	No. 2.	No. 3.
Dam and Headgate, Harriman Ditch—Part of south-east quarter of south-west quarter, section 35, township 4 south, range 70 west, and part of north-east quarter of north-west quarter, section 2, township 5 south, range 70 west, 11.84 acres. This property protects the head of the Harriman Ditch. We value it for other purposes at	.....	300.00	.....

Harriman Ranch—South half, section 4; south half of north-east quarter of section 4; south-east quarter, section 5; north-east quarter, section 9; north-east quarter of north-west quarter, section 9; east half of south-east quarter, section 9; north-west quarter of south-east quarter, section 9; all in township 5 south, range 69 west, 880 acres. 480 acres choice farm land at $95.00 an acre....	45,600.00	14,400.00	3,500.00
182.8 acres of land not under ditch, valued as pasture land.....	.....	1,828.00	.....
150 acres of good land under ditch, but not irrigable, from the Harriman ditch or reservoir, valued without water at.....	.....	3,750.00	.....
In regard to the 150 acres, we find that this land is under the Bergen ditch and also under the Soda Lakes, but we find that we did not obtain sufficient information in regard to this water supply to concede that it was as full and completely watered as other lands we have valued; therefore, no valuation has been placed upon the water rights mentioned as available for this land in this report. In addition to the above lands, amounting to 812.8 acres, there are 67.2 acres occupied by the Harriman reservoir. This reservoir is of so much greater valuation as an irrigation reservoir than for farm land, that we do not attempt to give its value as farm land and have not agreed on its value as an irrigation reservoir.			
56 Marston Lake Flume. In section 10, township 5 south, range 69 west, 303 acres.....	.....	200.00	.....
Marston Lake Reservoir—14 separate items in list furnished us comprising large reservoir which occupies most of the land mentioned. All the land covered by the reservoir is of greater value for an irrigation reservoir than for farming purposes, and we have not agreed on its valuation for such purposes. As to the lands around the margin of said reservoir, we find that there are 50 acres of good land worth	5,000.00	1,750.00	.....
100 acres valued only as pasture.....	.....	1,000.00	.....

Farm buildings on north side of ranch does not include reservoir structures or boat house	.....	.....	1,500.00

Cherry Creek Lands.

Sullivan Reservoir Site—East half of north-west quarter section 33, township 4 south, range 67 west, 80 acres. We are unable to value this 80 acres for any purpose except as pasture at this time, although we realize that the incompleted works thereon may give it a very much greater value for water works purposes, simply counting the land and ignoring any improvements	.....	$1,000.00	.....
Cherry Creek Gallery Lands—5 items comprising 144.7 acres. We find that in all, approximately, there is about 60 acres of good land, which we figure with water from the High Line Ditch and not in acre feet as in other cases	$6,000.00	3,600.00	.....
The above appraisement is on the basis that the company have $2,400.00 worth of water, all of which can be applied on this land. The value of the remaining 87 acres, classed only as pasture, mostly in Cherry Creek, is only	.....	500.00	.....

57 Cherry Creek Lands.

On the above lands are three dwelling houses, a large store house building, which evidently cost more than $10,000.00, and are not available as good income property at the present time, and while well constructed, brick, shingle roof, has been built for many years. They, however, can be made of some value, and our estimate is	No. 1.	No. 2.	No. 3. $2,500.00

Harriman Ditch Fencing—A strip of land 20 feet in width through the east half of south-west quarter and the south-west quarter of the south-east half, section 6, township 5 south, range 69 west, adjoining the right of way of the Arnett, now the Harriman Ditch.....	.....	50.00	.....
Various parcels, consisting of right of way of the 40-inch conduit on Platte Canon, commencing with three items on page 5 of schedule, comprising the items on page 6, and all items on page 7 of schedule, except the last two. This right of way was carefully examined in some portions, but we did not have the time to walk all over it, and we have decided to give it an average value; the average amounts to 120 acres.....	.....	6,000.00	.....
These parcels of land could be incorporated with adjoining lands for farm purposes, but are probably worth more as a right of way for some future purpose.			
The next item, seepage land, has all been appraised as pasture land in connection with other Marston Lake items.			

Respectfully submitted,
(Signed) J. B. McNEIL,
BURTON D. SANBORN.

58 Schedule of Distribution System Owned by the Denver Union Water Company, Agreed to by J. B. Hunter and W. F. Hawes, December 13, 1907.

NOTE BY BOARD.—The board understands that the compound three million gallon Gaskill pump now on Capitol Hill is the property of the City and County of Denver, and has valued it as part of this property, although not included in the above list, agreed to by J. B. Hunter and W. F. Hawes.

64 *Report on Value of Personal Property, by Hamilton and Reed.*

DENVER, COLORADO, December 12, 1907.

Report to the Board of Appraisers on the Denver Union Water Company as to the value of personalty, embodied in an inventory of material, supplies, furniture, fixtures, equipment, tools, farm produce, livestock, etc., made under and by instruction of the appraisers.

GENTLEMEN: Pursuant to your orders for an estimate of the value of the property in question, we beg to submit the following findings, which are set forth in detail on the following statement, and are agreed to by each of us as fair and equitable to both parties concerned, and take into consideration every item on the list except certain material ordered excepted by the board as per detailed list now in their possession, and except district books, last season's license books, price and equipment records, maps, plants and drawings, lease of office, unexpired insurance, etc., to be considered by your board.

79 Lake Cheesman lands, including the land on which the dam and reservoir are built, and surrounding lands, in all, 8,436 acres, more or less.

Rights of way for all pipe lines laid in private lands, the fee of which is not in The Denver Union Water Company.

District books, last season's license books, price and equipment records, maps, plans and drawings.

80 Eleventh. Since the date to which said appraisement referred, to-wit, October 20th, 1907, complainant has expended in betterments, improvements, extensions and additions to its properties and water system, as so appraised by said Board of Appraisers, the sum of two million, sixty-four thousand, six hundred thirty-one dollars and eight cents ($2,064,631.08), at the following times and for the following purposes:

Date.	Character of betterment, improvement or addition.	Amount.
1908	Conduits, Pipe and Pumping systems, miscellaneous	$197,924.64
	" " " " " "	122,018.07
1909	" " " " " "	544,417.11
1910	" " " " " "	609,299.24
1911	" " " " " "	409,599.35
1912	" " " " " "	161,856.57
1913	Conduits, pipe system and miscellaneous	19,516.10
1914	(to date) " " " "	
	Total	$2,064,631.08

The above expenditures represent the actual and reasonable cost and value of said betterments, improvements, extensions and additions, and each and every thereof was necessary and proper in order to provide the defendant the city and county of Denver and its inhabitants with an ample supply of water for all purposes, and to protect the city and county of Denver in its growth.

Twelfth. Complainant, prior to April 10th, 1910, pursuant to and in accordance with the provisions of Article XX of the Con-
81 stitution of the State of Colorado and the Charter of the city and county of Denver, prepared and caused to be submitted to the tax-paying electors of the city and county of Denver at the general election held May 17th, 1910, a franchise and contract to be entered into between complainant and defendant the city and county of Denver, providing upon reasonable and fair terms, for a continuance of the relation between the complainant and defendant the city and county of Denver, and the supplying of water by complainant to the city and county of Denver and its inhabitants, which said proposed ordinance and franchise was defeated and rejected by defendant the city and county of Denver at said election; there was at the same election submitted to the voters a proposition for the defendant the city and county of Denver to purchase the water system and property of complainant upon a new appraisement, which was likewise and at said election defeated and rejected. At the same election, and subsequent to the appraisement of fourteen million, four hundred thousand dollars ($14,400,000.00), there was initiated and submitted to the voters of defendant, the city and county of Denver, Section 264-A of the Charter, creating a Public Utilities Commission, composed of three members, the defendants Armour C. Anderson, Edwin Van Cise and A. Lincoln Fellows, and provided that the complainant should be offered the sum of seven
82 million dollars ($7,000,000.00) for its property theretofore jointly appraised at fourteen million four hundred thousand dollars ($14,400,000.00), and in case such offer should not be accepted by complainant, steps should be taken to construct and build a complete competitive water system at a cost of not to exceed eight million dollars ($8,000,000.00), which said Charter Amendment, being Section 264-A of the Charter, was adopted.

At a special election held in the city and county of Denver on February 17th, 1914, there was submitted to the electors and taxpaying electors of defendant a contract to purchase, by which the defendant the city and county of Denver was to purchase the water system and properties of complainant theretofore appraised, as hereinabove alleged, together with all betterments, improvements, extensions and additions thereto, at a price to be fixed by an appraisement, in which the Public Utilities Commission were to act as appraisers for defendant the city and county of Denver, and pending the consummation of said purchase complainant was to operate said water system upon a profit sharing basis yielding far less than a reasonable return to complainant upon the reasonable and actual value of its properties, and which said contract was prepared and proposed by The Retail Association of the Denver Chamber of Commerce, and which complainant agreed to accept and abide by if the same were voted favorably on by the tax-paying electors of
83 the city and county of Denver. Said contract to purchase was rejected and defeated at said election on February 17th, 1914.

At various times since April 10th, 1910, complainant has offered to sell its properties and water system as heretofore appraised by representatives of complainant and defendant the city and county of Denver, together with the betterments, extensions, improvements and additions thereto, as set forth and alleged in this bill, at a price to be fixed by any fair method of appraisement, but defendant the city and county of Denver and the Public Utilities Commission has refused to accept said offers and has made no attempt either to acquire the said properties and water system of complainant or to grant for a definite time a contract or franchise to complainant for the further supplying of water to defendant the city and county of Denver or its inhabitants, except as set forth in Section 264-A of the Charter.

Regardless of the offers and attempts heretofore made by complainant to have fixed the relations between complainant and the city and county of Denver concerning the continuance of supplying water to the defendant the city and county of Denver and its inhabitants for all purposes, or the sale of its properties, and of the rejection of said offers by the city and county of Denver and the refusal on its part to propose any terms or method for the continuance of
84 said supply of water, or the purchase of the properties of complainant, complainant has been compelled to and is now compelled to continue to serve the defendant the city and county of Denver and its inhabitants with water, because there is no other supply of water available to defendant or its inhabitants and a cessation of said service for a period of twenty-four hours would result in great suffering, damage and loss of life. Because of the necessity aforesaid, complainant has continued to so supply the city and county of Denver and its inhabitants with water, although under no legal obligation so to do, and although defendant the city and county of Denver has since April 10th, 1910, declared complainant to be a trespasser in the streets and public ways of the city and

county of Denver, but without waiving in any way its right to discontinue such service at any time, and to devote its property to other uses.

Defendants, and the inhabitants of the city and county of Denver, have no other source of water supply for themselves; no plans or specifications for the construction of a complete and independent water system as proposed under Section 264-A of the Charter, and no water or water rights even partially adequate for the purpose of supplying the city and county of Denver and its inhabitants with water. A complete and independent water system for the city and
85 county of Denver, even if possible of construction and assembly, could not be constructed in less than seven years from the date of the beginning of such construction, and during such construction the city and county of Denver and its inhabitants will be entirely dependent upon the properties and water system of complainant for their water supply and service. Regardless of the above facts and conditions, defendants have rejected every offer of complainant to sell its properties and water system to the city and county of Denver at a fair, reasonable and appraised price, or to have fixed the terms and rates for the continuance of the supplying of the city and county of Denver and its inhabitants with water, and have threatened and are threatening to destroy all, or a large part, of the property of complainant and its value and to acquire complainant to continue to devote its properties and water system to supplying defendant the city and county of Denver and its inhabitants with water, at rates and charges and upon terms which will not yield a fair or reasonable return upon the actual value of the property so required to be devoted to such public use, and without authorizing or permitting complainant to so continue, for a fixed and reasonable time of such duration as will permit it to protect its property during such enforced service, and receive compensation reasonable under all such conditions.

Thirteenth. Water rates and charges under the Leaflet Schedule
and the schedules prior thereto have during the corporate
86 existence of complainant at all times been payable in advance semi-annually on the first days of May and November of each year, and the fiscal year of complainant begins on the first day of November in each calendar year. Complainant now has and during the last fiscal year had 44,280 water consumers in the city and county of Denver connected with its water system and receiving their entire water supply for all purposes from complainant, and during the coming year from May 1st, 1914 to May 1st, 1915, the number of water consumers will be approximately the same. For the various completed fiscal years since the joint appraisement hereinabove referred to the financial operations of complainant have been as follows:

Year.	Gross earnings.	Operating expenses.	Taxes.	Net earnings without deductions for depreciation, obsolescence, etc.	Interest on bonded debt.	Net income or surplus.
1908	$1,067,388.22	$232,530.70	$91,947.28	$742,910.24	$513,759.32	$229,150.92
1909	1,168,808.86	255,360.16	95,301.98	818,146.72	513,995.48	304,151.24
1910	1,255,794.60	308,173.76	113,386.52	834,234.32	525,071.07	309,163.25
1911	1,337,500.57	325,053.53	117,132.90	895,314.14	536,537.41	358,776.73
1912	1,383,977.75	331,564.31	115,842.18	936,571.26	534,205.81	402,365.45
1913	1,373,337.90	352,242.42	117,146.62	903,948.86	540,944.82	363,004.04

In the foregoing financial statement no allowance or deduction has been made from gross earnings for depreciation, obsolescence or unusual contingencies to which the properties of complainant are liable, and which amount to not less than the sum of one
87 hundred and seventy thousand dollars ($170,000.00) annually, which said sum, together with operating expenses and taxes, should be deducted from the gross earnings to ascertain the net earnings and the annual rate of return or earnings upon the present actual value of the properties of complainant devoted to and necessarily devoted to the supplying of the city and county of Denver and its inhabitants with water.

Fourteenth. Since the appraisement hereinabove referred to, complainant has furnished to the city and county of Denver and its inhabitants, the following quantities of water:

Year.	Total gallons.	Maximum day.	Average per day.	Minimum day.
1908	16,006,600,000	58,100,000	43,700,000	33,900,000
1909	16,265,000,000	60,300,000	44,600,000	35,800,000
1910	17,933,800,000	68,800,000	49,100,000	37,600,000
1911	17,887,700,000	68,400,000	49,000,000	33,800,000
1912	15,839,400,000	64,400,000	43,300,000	32,600,000
1913	16,792,300,000	72,300,000	46,000,000	32,700,000

The per capita consumption per day during the foregoing years has been in excess of two hundred (200) gallons.

All of the water so supplied the city and county of Denver and its inhabitants was filtered water, pure, wholesome and potable.

The consumption of water for the year beginning May 1st, 1914 and ending May 1st, 1915, will be approximately the amount hereinabove set forth as furnished for the year 1913, and will
88 likewise be filtered water, pure, wholesome and potable.

Fifteenth. Neither defendant the city and county of Denver nor the Public Utilities Commission prior to August 11, 1913, made any attempt to examine investigate or value the properties and water system of complainant through capable or experienced men or engineers, or to investigate the possibility, feasibility or cost of constructing a complete independent plant or water system for defendant the city and county of Denver capable of supplying it and its inhabitants with all of the water necessary for all purposes.

On August 11th, 1913, the defendant the city and county of Denver and the Public Utilities Commission appointed one of its own members. A. Lincoln Fellows, and two other engineers, to-wit, C. P. Allen and Edmond C. Van Diest to inspect, examine, value and report upon the properties and water system of complainant and the plans and costs of construction of a new and complete water system for defendant the city and county of Denver capable of supplying it and its inhabitants with water for all purposes. Said three engineers so appointed entered immediately upon their duties and were continuously engaged therein until January 14th, 1914, at which time they presented to defendant the city and county of Denver and said Public Utilities Commission a complete and volu-

minous written report, setting forth the result of their labors
89 and investigation, which said report was not submitted, however, until after said Public Utilities Commission had requested said three engineers to eliminate from said report certain statements and valuations more favorable to complainant and its properties, than those contained in said report as filed.

Said Engineers in said written report to said Public Utilities Commission unanimously made the following statements in reference to the properties and water system of complainant:

We find the system to be generally in excellent working condition, well maintained and well managed, and adequate for supplying the city's present needs. The very thorough survey made by the Engineers of the Fire Underwriters' Association indicates that the system is, in general properly gridironed and the fire service satisfactorily supplied. If the report had been followed by rate revision, the rate should be as low in Denver as in any city in the United States for a similar risk.

The water system is in efficient operating condition and the water supply as pure as possible and adequate for all present needs. If the property is taken over by the city, no emergency measures for immediate additional supply, nor any other immediate construction or improvements will be necessary, excepting such extensions of the distributing system as growth and development in different parts of the city may require.

We have listed, but have not valued the water rights claimed by The Denver Union Water Company, as the courts have held that
90 water is the property of the consumer and the Company cannot be considered other than a "Carrier." Whether the Company has not acquired the prior or even the exclusive right to carry the water, defined in the list of appropriations, to the consumers, the courts only can decide. We desire to suggest that this is the only real point of controversy left, and that a compromise will enable the city to enter into possession of the property speedily, and eliminate the further heavy expense and tedious delays attendant upon a final adjudication through the courts, and settle a controversy which has already been pending since 1907.

The general purity of the water supply and the reduction in the number of typhoid fever cases as the filter plants were installed, is well illustrated on the chart of typhoid statistics appended. Notwithstanding the increase in population the number of deaths from typhoid fever in 1912 was the lowest in the history of the city.

If the public is not ready or willing to incur the risks of first providing its necessities or conveniences as communities grow, and is willing to allow a corporation or individual to under take the risk by granting a permit, and when this permit has expired desires to serve itself, all the risks having been overcome, if the rates paid have not provided a fair return for the full period of the permitted operation, then at least this deficiency must be included in the price to be paid for the property when the permit expires.

Your Committee has duly considered that the interest basis adopted (7% with 1% added for depreciation, or a total of 8%),

represents a fair earning at the present time, but may not represent a fair earning during the earlier periods of the Water Company's operations.

91 It would not be possible for the city of Denver to divert the water which the people of the city as consumers own, without compensating The Denver Union Water Company and The South Platte Canal & Reservoir Company for the destruction or loss of its property, used for conveying this water to the City, constructed at great expense for the sole purpose of supplying the community. It cannot be denied that if these companies were deprived of the right of Carriage and Storage by reason of changes in the diversion of the water, this property would be destroyed, as it is of such a character that it is not susceptible of removal or re-use, so that no material salvage value can be applied.

The attached list summarizes the value of that part of the property of The Denver Union Water Company and The South Platte Canal & Reservoir Company which we believe the city of Denver should own in connection with the water system and as an essential part of the property, either present or prospective.

We estimate the net value of the property as specified, exclusive of "Going Concern Value" or "Rights of Carriage of Water, as of November 1st, 1913, including all property necessary for the proper operation of the plant under municipal ownership to be $10,044,-778.31.

Free Water Supplied to the City of Denver by the Denver Union Water Company, during the year 1912.

Recapitulation.

Street Cleaning Department	37,350,000	gallons
Sewer Flushing	87,182,400	"
Automatic Sewer Flushers	1,292,100,000	"
Street Sprinkling Department	263,659,200	"
	1,680,291,600	"
Average per day	4,603,539	"

92 With these, and as the most important element of all, is the maintenance of a supply of pure water, well in excess of possible growing demand for domestic purposes, and for the agricultural development of the fertile lands to the east. It is already well known that the water supply available, and tributary to Denver from the eastern slope of the range, has been over appropriated, more reservoirs have been already constructed in several districts than the average flow, both normal and flood, will regularly fill.

And concerning the construction of a complete and independent municipal plant:

Estimates of Cost of Acquiring or Constructing a Complete Water System for the City of Denver, By Any of the Methods Proposed.

We cannot recommend the construction of a new system, for reasons hereinafter stated and for the further reason that considerable time will be required to secure an adequate supply, complete the legal details necessary to change the use from irrigation supply to a continuous domestic use, etc. and when secured surveys and preparations of construction plans will require at least a year's time. Tunnels, reservoirs, filters and conduit system for conveying the water to the city could not at the best be constructed in less than four or five years thereafter.

We cannot recommend the installation of a new distributing system. The cost of reconnecting the 44,000 services now in use is estimated approximately at $440,000.00. The cost to the consumers and citizens in inconvenience, temporary service interruptions, obstruction to traffic, damage to the many miles of paving and street surfacing, with probable serious fire risks, would be considerably greater, but is not susceptible of computation.

93 As elsewhere estimated, without allowance for delays in legal proceedings, it should be possible to construct a new water system complete in serviceable operation and providing service in 5 years.

Approximate cost:

Lands and Water Rights	$750,000.00
Reservoirs and Canals	2,500,000.00
Conduits	2,500,000.00
Hydro-Electric Plant	300,000.00
Filters	200,000.00
Distributing System	4,500,000.00
Engineering, contingencies & interest during construction	2,000,000.00
	$12,750,000.00

The plan can only be outlined briefly in a very general manner, and its feasibility indicated. If the Western Slope diversion and tunnel were found necessary, about $3,500,000.00 would be added to the cost, and as above includes a hydro-electric development.

The elements to be considered are: the inconvenience to the public, practicability, expense and time required, with their effect on rates. The inconvenience to the public consists in the interruption of service and serious impairment of general traffic conditions throughout the city during the time required to re-lay mains, make the necessary service connections, and re-lay the pavements, and also the additional time required to enable the Water Company to remove its own mains, hydrants, etc. after the city system had been installed. This would require another two years during which the streets and even the sidewalks in places would have to be torn up.

The indirect loss to the city in patched paving that would result would be as great, or greater, than the extra cost of the new service.

94 Your committee does not consider it impossible to install a complete new distributing system, nor do we believe that the health of the city would be affected by the opening of the streets, but we are convinced that it is not advisable to do so, that great inconvenience to traffic and to the public generally would result, and that the cost would be considerably in excess of the gross replacement value of the present system. Reconnecting 44,000 service connections would have to be included in the cost as it would be unjust to the consumer to require him to pay for a new connection.

The 'Economic Waste' involved in the destruction of the existing plant, which is in good operating condition, rendering adequate service, by the construction of a new municipal plant, is not to be contemplated, except as a last resort, and until every reasonable method of securing the present plant for the city on an equitable basis has been exhausted.

To the foregoing estimate of cost of a new system, we should properly add the loss of profit that would accrue to the city by the purchase of the existing plant during the period of new construction. Since the expiration of the franchise, the city has, by ordinance, ordered the Water Company to extend mains in several parts of the city. These the city would be under obligation to purchase.

All estimates of cost of a new system throughout must be mere approximations which experience would probably prove to be erroneous in many particulars.

Necessary information, such as surveys and detailed plans would develop, is wanting in every essential element.

Such a plan as heretofore suggested would naturally involve the purchase of Lake Cheesman by agreement or condemnation with the storage rights that are a part of it, and belong to The

95 South Platte Canal & Reservoir Company.

It would not be possible to construct so extensive a plant as that of The Denver Union Water Company within a period of time so short, as to virtually obviate any interest charges on the growing investment, even though all the plans and specifications had been completed.

Notwithstanding this favorable condition, we have estimated that five years would be required to replace the plant as it exists at present.

It would be equally unjust to destroy at least the major portion of the value of the property which has been rendering satisfactory service and can continue to render service to the public adequately and efficiently, by the construction of a competitive plant.

To refuse a fair capital return to any public utility corporation is but to smother enterprise, limit development and prevent growth of the community, and the welfare of its inhabitants.

The water and water rights belonging to complainant and used and necessarily in use supplying the defendant, the city and county of Denver and its inhabitants with water, and which were omitted

by said Engineers in their appraisement of the value of the properties of complainant, are of the present fair and actual value of three million, five hundred thousand dollars ($3,500,000.00), and were separately appraised by the joint appraisers of complainant
96 and the city and county of Denver in 1907 at the value of two million, eight hundred and forty-five thousand, nine hundred and twenty-five dollars ($2,845,925.00).

The "Going Concern Value" omitted by said Engineers and which is an integral and necessary part of the unit value of the properties and water system of your complainant, amounts to not less than fifteen per cent (15%) of the total value of the physical properties and water rights of complainant.

In the above described investigation, inspection and valuation of the properties and water system of complainant by defendant, the city and county of Denver, the Public Utilities Commission and the Engineers appointed by said Public Utilities Commission, complainant afforded to said Engineers and said Public Utilities Commission all facilities and opportunities for the investigation and valuation of said property and water system, and also the inspection and examination of all records, statements and data possessed by the complainant in reference thereto.

The inspection, examination and valuation aforesaid by said Engineers appointed by defendant the city and county of Denver and said Public Utilities Commission was entirely ex parte and without notice or opportunity to complainant to participate therein or to be present at meetings of said Engineers, or to present to said
97 Engineers on behalf of complainant testimony, data, information or argument concerning the extent, quality and value of the properties and water system of complainant. Had such opportunity been so afforded to complainant the valuation placed upon the properties of complainant by said Engineers would have approximated the appraised values fixed by the joint appraisers appointed by the complainant and defendant the city and county of Denver in 1907.

In September, 1913, complainant, being desirous of having its properties and water system completely and accurately re-inventoried and re-valued, as of the present time, and in order to adjust the inventory and valuation of its properties and water system under the appraisement of 1907 and in accordance therewith to date, employed two civil and hydraulic Engineers of national standing of the highest integrity and the widest experience, to-wit, George G. Anderson of the city and county of Denver, state of Colorado, and Leonard P. Metcalf, of Boston, Massachusetts, to completely and thoroughly inspect and inventory all of the properties and water system of complainant used and necessarily being used in supplying the City and County of Denver and its inhabitants with water, and to fix the actual present value of said properties and water system. Said Engineers, Anderson and Metcalf, were from September 13th, 1913 to
98 February 14th, 1914, a period of approximately five months, continuously, with agents and representatives selected by them, engaged in inspecting inventorying and valuing said prop-

erties and water system of complainant. Said Anderson and Metcalf completed and filed with complainant a detailed and comprehensive inventory of all of the property constituting the water system of complainant and now used and necessarily used in supplying the defendant the city and county of Denver and its inhabitants with water, and fixed and determined its actual present value at sixteen million, sixty-three thousand dollars ($16,063,000.00).

Sixteenth. Prior to the 1st day of February, 1914, the Public Utilities Commission caused to be prepared a certain bill for an ordinance to reduce and regulate the charges heretofore and in the year 1913, and for several years precedent thereto, charged by complainant for supplying water to the city and county of Denver and its inhabitants. Said bill for an ordinance, so prepared under the direction of the Public Utilities Commission, was introduced in the Council of defendant, the city and county of Denver, and on the 3rd day of March, 1914, was passed and enacted by said City Council, approved and published in accordance with the Charter of defendant, city and county of Denver, and is known as Ordinance No. 26 of the Series of 1914, a true copy of which is hereto attached as Exhibit
99 "A" and as a part of this bill of complaint. Said ordinance No. 26 of the Series of 1914, was prepared and enacted without consultation or conference with complainant; without any notice to complainant or any opportunity afforded complainant to be heard in reference to the matters therein contained, and the effect thereof on the income and properties of the complainant. Neither the defendant, the city and county of Denver, or the Public Utilities Commission, or any member thereof, or the Council of the city and county of Denver, or any member thereof, attempted, prior to the enactment of said ordinance, to investigate the fairness or justness of the rates therein provided to be adopted by complainant, or the effect thereof on the income or properties of complainant. Said ordinance was conceived, prepared, drafted and enacted without reference to the fairness of the rates therein prescribed, or the effect on the properties and income of complainant, but for the purpose of crippling and hampering complainant in the operation of its water system and to depreciate the earning capacity and value of the properties and water system of complainant, in order to enable defendant, the city and county of Denver, and said Public Utilities Commission, to purchase and acquire the properties of complainant at less than fair actual present value, and less than the value heretofore fixed and determined through the joint appraisement of 1907
100 aforesaid, and the values ascertained by the Engineers appointed by said Public Utilities Commission.

The schedule of rates contained and set forth in said Exhibit "A" follows generally the items and form of schedule "A" and the "Leaflet Schedule" and which later schedule constituted the basis of charges by complainant to the city and county of Denver and its inhabitants for the year 1913, and for several years previous thereto. The purpose and effect of the enactment of said Exhibit "A" was declared by defendant, the city and county of Denver and the members of the Public Utilities Commission and members of the Council,

to be to reduce the rates under said Leaflet Schedule twenty per cent (20%) horizontally.

Seventeenth. Said Exhibit "A" in fact, reduces the charges to be made by complainant, and the gross earnings to be derived thereunder, in excess of twenty-one per cent (21%) on the general list of items, and also provides that certain water and service shall be supplied and rendered by complainant to defendant, the city and county of Denver, without charge, which said water and service were and are of the reasonable value, and under said Leaflet Schedule of approximately one hundred thousand dollars ($100,000.00) per year, and the water and service so required to be rendered free by complainant to the city and county of Denver for the year beginning May 1st, 1914 and ending May 1st, 1915, will be worth the sum of
101 one hundred thousand dollars ($100,000.00).

Exhibit "A" likewise provides for certain other free service and water to the inhabitants of the city and county of Denver, and fixes terms and conditions for certain services which would make it impossible for complainant to collect any charge therefor. Exhibit "A" fixes a charge of $18.00 per year for every hydrant, which is a reduction of $4.50 per year per hydrant from the lowest charge ever made by complainant to the city and county of Denver for such service and which is more than $7.00 per hydrant per year less than the reasonable and fair charge for said hydrant service.

Eighteenth. In case said Exhibit "A" is enforced against complainant, and complainant is permitted to charge only the rates therein fixed for the coming year, beginning May 1st, 1914, and ending May 1st, 1915, the gross earnings of complainant for said year from the operation of its properties and water system used, and necessarily used in supplying defendant, the city and county of Denver and its inhabitants with water, will be more than two hundred eighty-nine thousand, two hundred and fifteen dollars ($289,215.00) less than for the fiscal year 1913, which will likewise constitute the reduction in the net income of your complainant, because the operating expenses, taxes, depreciation and other deductions to
102 which complainant is legally entitled, would remain and be the same in the year 1914-1915 as they were in the year 1913 and as hereinabove alleged. The number of water consumers who will be supplied, and who must be supplied through the properties and water system of the complainant, for the year 1914-1915, will be the same as they were for the year 1913. The amount of water consumed will be approximately the same, and owing to the fact that charges to defendant, the city and county of Denver and its inhabitants, are almost entirely upon a fixed schedule of rates, it is possible to figure almost the exact income to be derived by complainant from the operation of its properties for the year 1914. Under Exhibit "A" the result of the operation of properties of complainant will be as follows:

May 1st, 1914 to May 1st, 1915.

Gross earnings.	Operating exp.	Taxes.	Depreciation and obsolescence, etc.	Net earnings.
$1,084,122.53	$333,045.06	$120,000	$170,000.00	$461,077.47

The depreciation and obsolescence charge above set forth includes only a reasonable allowance for the actual depreciation and obsolescence upon the properties and water system of complainant, by its nature necessarily subject to depreciation and obsolescence and employed and used by complainant in the supplying of the city and county of Denver and its inhabitants with water.

103 The net earnings of complainant under Exhibit "A" and the rates, charges and terms fixed therein, if the same is enforced, will for the year May 1st, 1914, to May 1st, 1915, return to complainant upon the present actual value of the properties and water system of complainant, used and necessarily used in the supplying of the city and county of Denver and its inhabitants with water for all purposes during the aforesaid year, less than two and eighty-eight hundredths (2.88%) per cent.

Nineteenth. Each and every of the defendants have declared, and are declaring, their purpose of enforcing and threatening to enforce, all of the terms and provisions of said Exhibit "A" on and after May 1st, 1914, and are advising and urging the inhabitants of the city and county of Denver not to pay rates or charges to complainant except in accordance with said Exhibit "A" and the rates therein fixed. Defendants, and the inhabitants of the city and county of Denver will, unless restrained and prevented by an order of this court from enforcing Exhibit "A", refuse to pay to complainant other reasonable charges for the water and services supplied to them by complainant, and as fixed in the Leaflet schedule, or any charges other than those fixed in said Exhibit "A".

Twentieth. By the Fifth Amendment of the Constitution of the United States, it is provided that no person shall be deprived

104 of property without due process of law, and that private property shall not be taken for public use without just compensation; and in the Fourteenth Amendment to the Constitution of the United States it is further provided that "no state shall make or enforce any law which shall abridge the privileges or immunities of the citizens of the United States, nor shall any state deprive any person of life, liberty or property without due process of law, nor deny to any person within its jurisdiction the equal protection of the law." This is a case arising in equity under the Constitution of the United States, and the judicial power of this Honorable Court extends to and embraces this case and its issues, as complainant is informed and believes, and the issues herein set forth involve federal question under said Constitution of the United States. By reason of the acts and facts and things herein alleged the rates provided in Exhibit "A" are unreasonable, unjust, fraudulent, confiscatory, ambiguous, uncertain and unintelligible, and if enforced will compel complainant to conduct its business and operation without fair remuneration, and as to certain portions of said business and operations and supplying of water without any remuneration or compensation. Said rates and terms as provided in said Exhibit "A" are violative of and prohibited by each and all of the said provisions of said Constitution of

105 the United States, and by reason of and under said provisions are null and void.

Complainant, under said Exhibit "A" will be compelled to furnish water to defendant the city and county of Denver and its inhabitants, at less than the fair, reasonable and just value of the services rendered, and by the enforcement of said rates and terms of said Exhibit "A" complainant will be deprived of property without due process of law, and will be deprived of property without any process of law in violation of the provisions of the Constitution of the United States, and the property of complainant will be taken for public use without just compensation and in some instances without any compensation, and by and through the enforcement of said Exhibit "A" the privileges and immunities of complainant will be abridged and the equal protection of the law denied to it in violation of the provisions of the Constitution of the United States.

Exhibit "A" and the rates and terms purported to be fixed thereby, were and are wholly void, null, unjust, unreasonable, fraudulent and unconstitutional under the provisions of the Constitution of the United States, oppressive, confiscatory, ambiguous, uncertain and unintelligible, and said rates do not permit of or provide for a just or fair or reasonable compensation for water and service to be supplied after May 1st, 1914, and during the year from May 1st, 1914
106 to May 1st, 1915, to the city and county of Denver and its inhabitants.

Twenty-first. Section 2 of Exhibit "A" was and is unreasonable and unjust and unconstitutional under the provisions of the Constitution of the United States herein referred to, and confiscatory, and is greatly inadequate as a compensation to complainant for the services therein contemplated; such services contemplated for said hydrant rentals, excluding any service except fire service and protection, are reasonably, fairly and justly worth the sum of more than $25.00 per hydrant per year, and the value of complainant's property and water system actually in use for this part of such service, over and above and in excess of the value of the property of complainant required and necessary for all other uses of water supplied by it in the premises, has been, and will during the year from May 1st, 1914 to May 1st, 1915 be, largely in excess of the principal sum which, even at six per cent. per annum income, would produce said rate or revenue of $25.00 per year per hydrant.

The gross income received by the complainant for the year ending May 1st, 1914, to-wit: one million, three hundred sixty-three thousand, one hundred twenty-one dollars and eighty-six cents ($1,363,121.86), did not yield a fair interest or return upon the actual value of the property, actually and necessarily used in supplying
107 the city and county of Denver and its inhabitants with water, after deducting operating expenses, taxes and depreciation, obsolescence and other deductions to which complainant is entitled.

Twenty-second. Included in the properties and water system of complainant are certain physical properties or portions of said water system, which are, by their nature and the uses to which they are subjected, constantly undergoing depreciation. Complainant is entitled to have its property devoted to the public use of supplying the city and county of Denver and its inhabitants with water, re-

main unimpaired in value and to receive for the water supplied and services rendered a reasonable return upon the value of the property so devoted to said uses, and a sufficient amount to protect said property against depreciation and other impairments of value. It is now a common practice for Companies of the character of complainant to make an annual allowance for insurance against destruction by fire or other casualty, for depreciation, aging and wearing out and obsolescence of plant, and to provide a fund for replacing said property when destroyed or worn out and when it has become obsolete. There is continually in progress in all water systems, a waste and depreciation due to its use, ravages of time and action of the elements, a portion only of which wear and decay can be offset by ordinary and current repairs. All the property thus
108 depreciated or worn out must be replaced sooner or later if the integrity of the water system is to be maintained, and the cost of re-placing such portions of a water system enter into the cost of furnishing, supplying and delivering water. To maintain a water system and to maintain the properties and water system of complainant, it is necessary to provide for, (*a*) ordinary depreciation, and (*b*) obsolescence of portions of the plant. The necessity of making an annual allowance to cover depreciation and obsolescence arises from the fact that the item (*b*) above must be made periodically rather than currently or annually, although the actual wearing out is constantly progressing. The re-placing of worn out and obsolete portions of a water system as necessity arises therefor, is as essential to the maintenance of the water system in its integrity as is the making of current repairs. The practice of making an annual allowance for depreciation and obsolescence has become so well established, and is so clearly nece-ssary and right, that public service commissions in many states, in the instructions which they issue in relation to the keeping of accounts and making of repairs of public service corporations, expressly provide for a separate statement of such items, and the term "obsolescence" is now and has been for many years last past generally accepted by accountants as the proper term as indicating the loss resulting from dis-
109 carding property, plant and machinery before it is worn out, and the substitution therefor of improved property, plant and machinery by means of which any commodity can be more economically furnished and supplied. Such depreciation and obsolescence do not effect in any way the ability of complainant to supply the water needed by the city and county of Denver and its inhabitants, nor will they do so, but as hereinbefore alleged they constitute an annual expense to complainant in supplying said water and rendering said service. Complainant is also entitled to an allowance to cover extraordinary casualties and contingencies, such as fire and flood, which have occurred and may occasion loss and damage to the property and water system of the complainant, and which require expenditures in order to preserve the integrity of a water system and the property and water system of complainant. To cover, provide for and compensate complainant for depreciation, obsolescence and other deductions hereinabove stated, to which com-

plainant is legally entitled, complainant will be entitled, during the year from May 1st, 1914 to May 1st, 1915, to an allowance of not less than one hundred and seventy thousand dollars ($170,000.00), which sum is a reasonable amount to provide for the items of expense herein referred to and to preserve the integrity and value of complainant's property and water system.

Twenty-third. It is essential, meet, right, proper and neces-
110 sary to the rights of complainant, present and future that this court, or your honors, by decree, determine the actual and reasonable value of the property and water system of complainant now devoted to, and which will be used during the year from May 1st, 1914 to May 1st, 1915, in, the supplying of water and the rendering of service in connection therewith to defendant, the city and county of Denver and its inhabitants, including its going concern or assembled value, and also what the amount of annual depreciation of the property of complainant by natural use and wear and tear, and reasonable allowance for obsolescence, as well as the amount to which complainant is entitled to replace portions of its property which might be destroyed by extraordinary casualty, and what will be during said year from May 1st, 1914, to May 1st, 1915, a reasonable and just income to it, based upon such values, and what will be a reasonable amount to be allowed for taxes and operating expenses during said year, and what will be the fair value of the services rendered by complainant in the premises for said year beginning May 1st, 1914, and ending May 1st, 1915.

Eliminated by amendment filed May 13, 1914.

Twenty-fourth. Neither the Council of the city and County of Denver, or any of the members thereof, who passed or acted upon Exhibit "A," had any right, power or authority whatsoever to consider, enact or approve said Exhibit
111 "A" under Article XX of the Constitution of the state of Colorado, or of the Charter of defendant, the city and county of Denver, and each and every act and pretended act of said Council, and the members thereof, in reference to said Exhibit "A," is and was at all times of no effect whatsoever. Said Exhibit "A" is null and void and of no force or effect whatsoever because not legally passed or adopted by the Council of the city and county of Denver, or any of the members thereof, having the power to act in the premises, and neither the Council of the city and county of Denver or any of the members thereof, had any right, power or authority to fix or attempt to fix the charges for services rendered and to be rendered by the complainant.

Twenty-fifth. All taxes heretofore paid by complainant, and from year to year, have been the taxes duly and legally assessed against the property of complainant, constituting a lien thereon, and which it was obligated to pay. All expenditures for operations heretofore made by complainant from year to year as herein set forth, are the actual, necessary and reasonable charges incurred in the operation of

the properties and water system of complainant for the purpose of supplying the city and county of Denver and its inhabitants with water.

Twenty-sixth. Under section 4 of Exhibit "A" the defendants herein, and each of them, are threatening to arrest and fine
112 complainant, and any of its officers who may attempt to collect rates other than those set forth in said Exhibit "A", or to do anything contrary to the provisions of Exhibit "A" and unless said defendants are restrained by this Honorable Court from so doing, said defendants will cause the complainant, and its officers, to be arrested and fined in numerous instances and charged with the violation of section 4 of said Exhibit "A".

The enforcement of section 4 of Exhibit "A" will result in a denial to complainant of the equal protection of the laws and render its property liable to be taken without due process of law, because complainant is only allowed a hearing on the claim of the unconstitutionality of Exhibit "A" and the provisions thereof at the risk, if mistaken, of being subjected to enormous, unusual and confiscatory penalties, resulting in the possible confiscation of a large part of its property.

Upon the refusal of any of the inhabitants of the city and county of Denver to pay the fair and reasonable rates charged for water supplied and services rendered to them, complainant will be obliged to begin numerous suits to collect said fair and reasonable rates, and Exhibit "A" and the rates therein provided will be made the excuse and justification by said water consumers for not paying said fair and reasonable rates.

The amount to be collected from each of the forty-four
113 thousand, two hundred and eighty (44,280) consumers taking their water supply from complainant is in most individual instances so small as to preclude the institution of litigation to collect the same, because of the cost involved, and in many instances complainant, having no security for the payment of said water charges, will be unable to effect a collection of the same.

Unless defendants and the inhabitants of the city and county of Denver be, by the orders and decrees of this court restrained from executing and enforcing said Exhibit "A", complainant will suffer great and irreparable injury, and a multiplicity of suits will result. Complainant has no adequate remedy at law for the redress of the injuries which will be inflicted upon it, and its property and officers, by the enforcement, or the attempt to enforce Exhibit "A", and it is necessary to protect the complainant's rights and property that a court of equity shall interfere with its power of preventing injury.

In consideration whereof, and inasmuch as complainant has no plain, speedy and adequate remedy at law in the premises, and can have no adequate relief except in this court, and to the end that defendants, and each of them, may make, if they or he can, full disclosure and discovery of their alleged claims and assertions and rights in the premises, and according to the best and utmost of their memories, knowledge, information and belief, full,
114 true, direct and perfect answer make to the matters hereinbefore stated and charged, complainant has brought this

action and waived verification or affirmation to the answer of defendants. Complainant prays that this court, and your Honors, may decree as follows:

First. That the writ of subpœna may be granted unto complainant, directed to the defendants herein named, to-wit: The city and county of Denver, a corporation; J. M. Perkins, Clair J. Pitcher, Alexander Nisbet, John B. Hunter and Otto F. Thum, as Commissioners, members of and constituting the Council, of the city and county of Denver; J. M. Perkins, as Mayor and Commissioner of Social Welfare of the city and county of Denver; Clair J. Pitcher, as Commissioner of Finance of the city and county of Denver; Alexander Nisbet, as Commissioner of Safety of the city and county of Denver; John B. Hunter as Commissioner of Improvements of the city and county of Denver; Otto F. Thum, as Commissioner of Property of the city and county of Denver; James F. Markey, as Auditor of the city and county of Denver; Armour C. Anderson, Edwin Van Cise and A. Lincoln Fellows, as members of and constituting the Public Utilities Commission of the city and county of Denver, and each of them, thereby commanding them, and each of them, at a certain time and under a certain penalty therein to be named, personally to be
115 and appear before this Honorable Court then and there to answer unto all and singular the matters aforesaid (not under oath or affirmation, all answers under oath or affirmation being hereby expressly waived), according to the practice and rules of this court, and to stand and abide by and perform such orders, directions and decrees as shall be made herein, and as to your Honors shall seem equitable and just.

Second. That said Ordinance No. 26 of the Series of 1914, Exhibit "A", as passed by the council of the city and county of Denver, on March 3rd, 1914, was and is unconstitutional, null and void and of no effect whatsoever, and that all further action thereunder be forever enjoined.

Third. That complainant is entitled to rates for supplying water and rendering service to the city and county of Denver and its inhabitants, for the fiscal year commencing May 1st, 1914, and ending April 30th, 1915, so fixed that they will in the aggregate afford a just, fair and reasonable compensation for the water supplied and services rendered, based upon the value of the property of complainant necessarily used therefor, and that will yield a sufficient annual income to complainant to pay its operating expenses and taxes and an annual sum for depreciation of its property and water system, and for obsolescence, and to provide for the replacement of portions of its property liable to be destroyed by extraordinary
116 casualty, and to realize, in addition a net earning or income in excess of eight per cent. per annum or such other rate as to the court may seem fair and reasonable upon the value of its property and water system in actual use in supplying the said city and county of Denver and its inhabitants with water, and that the value of such property is at least the sum of seventeen million dollars ($17,000,000.00).

Fourth. That defendants and each of them, and all consumers of

water in the city and county of Denver, and the agents, representatives and attorneys of each of them, be, perpetually at the conclusion of this litigation, enjoined from enforcing or attempting to enforce, said Ordinance No. 26 of the Series of 1914, Exhibit "A", and from bringing or causing to be brought, or prosecuting suit or action against the complainant, in law or in equity, to enforce said Exhibit "A", or for any other purpose on account of the failure or refusal of complainant to conform to the rates intended to be prescribed in said Exhibit "A".

Fifth. What the value of the property and water system of complaint is in use, and necessarily in use in supplying water to the city and county of Denver and its inhabitants, including in such value the fact that complainant has an established and going business, and to determine a reasonable and just net income to complainant based upon the value of its property, and what was and

117 is a reasonable amount to allow complainant for taxes on such property, and what were and are reasonable amounts to allow complainant for annual operating expenses and annual depreciation of plant, obsolescence and replacement of portions of its plant liable to be destroyed by extraordinary casualty, and what was and is the reasonable value of the services rendered by complainant to the city and county of Denver and its inhabitants, during a fiscal year.

Sixth. That a preliminary or interlocutory injunction be immediately granted, restraining and enjoining defendants, and each and all of them, and all consumers of water from the water system of complainant, together with their agents, representatives and attorneys, pending this litigation, from enforcing or attempting to enforce said Ordinance No. 26 of the Series of 1914, or any of the terms thereof, or from bringing or causing to be brought, or prosecuting any suit or action against complainant, or any of its officers, agents or representatives, in law or in equity, to enforce said Ordinance No. 26 of the Series of 1914, or for any other purpose, on account of the failure or refusal of complainant to conform to the rates, charges and terms intended by said Ordinance No. 26 of the Series of 1914 to be prescribed, and pending the ordering of said preliminary or interlocutory injunction and the hearing thereon, that a restrain-

118 ing order covering the matters herein prayed for be made.

Seventh. That complainant have such other and further relief as to this court and your Honors may seem right in the premises, together with complainant's costs of suit.

THE DENVER UNION WATER COMPANY,
By W. P. ROBINSON, *President.*
GERALD HUGHES,
CLAYTON C. DORSEY,
Solicitors for Complainant.

STATE OF COLORADO,
City and County of Denver, ss:

W. P. Robinson, of lawful age, being first duly sworn, on his oath, deposes and says:

That he is the President of the complainant, The Denver Union Water Company; that said complainant is a corporation and for that reason he makes this verification in its behalf; that he has read the foregoing bill of complaint and knows the contents thereof; that the same is true of his own knowledge, except as to matters therein stated on information and belief, and as to those he believes it to be true.

W. P. ROBINSON.

Subscribed and sworn to before me this 29th day of April, A. D. 1914. My commission will expire October 31st, 1914.

[NOTARIAL SEAL.] WALTER E. WILMOT,
Notary Public.

119 EXHIBIT "A."

By Authority.

Ordinance No. 26. Series 1914.

Initiated Bill for an Ordinance to Regulate Charges for Water Furnished the City and County of Denver and its Inhabitants by the Denver Union Water Company. While said Company shall Continue so to do, as a Tenant by Sufferance, and to Prohibit Discriminatory Rates and Charges and Provide a Penalty for Violation.

Whereas, The Denver Union Water Company is and has been since April 10, 1910, without a franchise and a mere tenant by sufferance of the streets of the City and County of Denver and has been during said time supplying said City and County and its inhabitants with water for divers uses and purposes, but at rates that are excessive and that should be reduced and regulated accordingly; now therefore.

Without in any manner recognizing said The Denver Union Water Company's right to occupy the streets of the City and County of Denver or to continue its service as a water carrier, but for the purpose of regulating and reducing the charges made by it during the time it shall further act as a water carrier and tenant by sufferance of said streets, to the end that the people may be properly and economically served.

Be it enacted by the Council of the City and County of Denver:

Section 1. That from and after the date of the passage and approval of this ordinance the rates of charge permitted to be made and collected by The Denver Union Water Company for water served, delivered and consumed by the City and County of Denver and the inhabitants thereof, shall be as follows and no more in any event, which shall constitute a schelule of semi-annual water rates payable in advance on the first day of May and November of each year, to-wit:

Alcohol, each barrel manufactured	$.03
Ale cellar, $6.40 to	12.80
Bakery, each oven, $3.20 to	16.00
Barber shop, first chair	2.55
Barber shop, each additional chair	.95
Barber baths, each	4.80
Bath, in private house, with heating apparatus, first bath tub	1.60
Each additional bath tub	.95
Bath private house, without heating apparatus	.65
Bath in boarding or tenement house of 15 rooms, or less	1.60
Bath in boarding or tenement house of over 15 rooms	3.20
Bath, public, hotel, saloon, sporting house, restaurant or club house	3.20
Beer, each barrel brewed	.03
Beer house, $6.40 to	12.80
Beer pump	3.20
Billiard tables, each	.95
Boarding or tenement house, per room	.45
But no less than	3.20
Bookbindery, not less than	3.20
Bowling alley, not less than	3.20
Bottling Works, $8.00 to	12.80
Brick work, per 1,000 kiln count	.06
Brick yard, each gang of hands	6.40
Camphene, each barrel manufactured	.03
Candle manufactory, $16.00 to	160.00
Candy manufactory, $5.20 to	24.00
Church, $1.60 to	4.80
Church, Baptist, for baptistry, $1.60 to	4.80
Cigar manufactory, per hand	.65
But no license less than	3.20
Club room, $9.60 to	32.00
Coffee saloon, $4.80 to	9.60
Confectionery, $4.80 to	19.20
Concrete, per cubic yard	.06
Concrete, per cubic yard, street paving	.04
Cow	.35
Cows, over five head, each	.25
Distillery, each barrel distilled	.03
Dram shop or saloon, $8.00 to	24.00
Dyeing or scouring, $8.00 to	24.00
Forage	.95
Fountain for six months, running not more than four hours per day—	
1 opening, 1-16 inch diameter	9.60
1 opening, ¼ inch diameter	16.00
1 opening, 3-16 inch diameter	25.60
1 opening, ¼ inch diameter	32.00
1 opening, 5-16 inch diameter	38.40
1 opening, ⅜ inch diameter	48.00

1 opening, 7-16 inch diameter	60.00
1 opening, ½ inch diameter	76.00
Fountain, vegetable, $4.80 to	8.00
Fountain, fish, $16.00 to	25.00
Fountain in drug store, opening not to exceed ⅛ inch diameter	25.00
Hall, $1.60 to	9.60
Hat manufactory, $4.80 to	24.00
Horse in private stable	.95
Hose, for livery or sale stable	12.80
Hose for livery stables—	
Not over 25 single stalls	12.80
Over 25 and up to 40 single stalls	16.00
Over 40 and up to 50 single stalls	24.00
Over 50 single stalls	32.00
Hotel, per room	.48
Ice cream saloon, $4.80 to	12.80
Laboratory, $6.40 to	32.00
Laundry, $6.40 to	95.00
Laundry, Chinese, not less than	8.00
Livery stable	.65
Lunch, in saloons, $4.80 to	9.60
Malting, per 100 bushels	.65
Motor for church organ, $8.00 to	12.00
Officers and banks, $1.60 to	9.60
Oyster saloon, $4.80 to	9.60
Packing house, $12.80 to	160.00
Photograph gallery, $6.40 to	12.80
Plastering, per 100 square yards	.32
Porter cellar, $6.40 to	12.80
Rectifying whisky, per 100 barrels	1.95
Residence, occupied by one family only—	
1 to 4 rooms	1 60
5 to 6 rooms	1.90
7 to 8 rooms	2.25
9 to 10 rooms	2.55
11 to 12 rooms	2.90
13 to 14 rooms	3.20
15 to 16 rooms	3.50
17 to 18 rooms	3.75
19 to 20 rooms	4.15
Residence used as boarding house or tenement house, of 10 or more rooms, per room	.48
Residence used as boarding or tenement house of less than 10 rooms	3.20
Rooms in blocks or over business houses	.48
Restaurants, $8.00 to	32.00
Sale stable, per stall	.65
But no license less than	12.80
School, including all uses of water except for boilers, motors and irrigation, for every scholar	.04

Store rooms and shops, $1.60 to	95.00
Store rooms and shops—	
12½ feet front or less	1.60
Over 12½ feet front to 18 feet front	2.50
Over 18 feet front to 25 feet front	3.75
Over 25 feet front to 37½ feet front	4.80
Over 37½ feet front to 50 feet front	6.40
Over 50 feet front, special rates.	
Stores—	
Confectionery store, $4.80 to	12.80
Drug store, $4.80 to	9.60
Liquor store, $4.80 to	9.60
Meat store or butcher shop, $4.80 to	9.60
Saloons, $8.00 to	24.00
Slaughter houses, $8.00 to	160.00
Soap manufactory, $32.00 to	240.00
Soda manufactory, $12.80 to	64.00
Sprinkling and washing pavements or sidewalks where irrigation rates are not paid, per foot run	.06
Starch manufactory, $16.00 to	64.00
Steam boilers, running 24 hours per day, per square foot of fire surface	.12
But no license less than	8.00
Steam boilers, for heating buildings or tenement houses only, per square foot of fire surface	.03
But no license less than	6.40
Steam boilers for heating private residence	3.20
Stock yard, $8.00 to	160.00
Stone work, per perch	.03
Sugar refinery, $96.00 to	960.00
Tannery, per vat	1.90
But no license less than	8.00
Tenement, per room	.48
But no license less than	3.20
Tobacco manufactory, per hand	.65
But no license less than	3.20
Tumbler washer in drug store	25.00
Urinal basin or trough, $1.60 to	6.40
Vault for residence	1.25
Vault, accommodating double house or more than one tenement, each tenant	.95
Vault, for tenement or boarding house, for every 15 rooms or less	1.60
Vault for bar room or saloon	1.60
Vinegar, for each barrel manufactured	.03
Washing bottles, $1.60 to	6.40
Washing barrels, per barrel	.03
Washing meat, $16.00 to	160.00
Washing vehicle in private stable, not less than	1.60
Water closet, private house, first bowl	1.60
Water closet, private house, each additional bowl	.95

Water closet, in boarding or tenement house of 15 rooms or less	1.60
Water closet, in boarding or tenement house of over 15 rooms	3.20
Water closet, in hotel, club room restaurant, saloon, barber shop or sporting house	3.20
Water closet, for use of two or more stores or houses	3.20
Wine cellar, $6.40 to	12.80

Special Rates.

Irrigation of lots, including sidewalks and trees, only through hose with nozzle not to exceed one-quarter of one inch in diameter, to be used only within the hours specified on the license and never during a fire or conflagration, 17½ cents per front foot for the season. Where irrigation is used outside of property lines along the side of irrigated corner lots, the frontage is counted to include one-half lot additional. No license for irrigation will be issued for less than the season rate, from May 1st to November 1st.

Meter Rates.

(Payable Monthly.)

1,000 to 15,000 gals. per month 13½ cents per 1,000 gals.
15,000 to 30,000 gals. per month 12½ cents per 1,000 gals.
30,000 to 60,000 gals. per month 12 cents per 1,000 gals.
60,000 to 150,000 gals. per month 10½ cents per 1,000 gals.
150,000 to 315,000 gals. per month 9½ cents per 1,000 gals.
315,000 to 637,500 gals. per month 9 cents per 1,000 gals.
637,500 to 1,500,000 gals. or over per month 8 cents per 1,000 gals.
City for any purposes 6 cents per 1,000 gals.
Minimum meter rate for business premises, $2.40 per month.
Minimum meter rate for residence, 20 cents per month.

Where water is paid for all purposes on premises there will be no additional charge for a stand pipe for fire protection.

Where The Denver Union Water Company's water is not used, a special rate will be made for such stand pipes, to be reasonable as construed with the foregoing.

No charge to be made for premises vacant for a space of two weeks or more; no charge for readiness to serve on any account; no discriminatory or preference rates to be given any consumer on any account whatever.

The Denver Union Water Company shall within thirty days after demand, upon payment of the cost thereof, install a meter for any person desirous of using water from said company by meter.

Section 2. For every hydrant now set and in commission, and for those which may thereafter be ordered by the Council to be set upon existing mains or upon extensions thereof, the City and County shall

pay to said Company the sum of eighteen dollars per annum, one-half the first day of May and one-half the first day of November of each calendar year, provided said hydrant rental shall include all water consumed or needed by the City for the following purposes. In court house, city hall and fire department houses, for flushing of sewers and gutters and for sprinkling of streets and washing of streets and sidewalks.

Section 3. That all charges against vacant houses and stores during periods of vacancy, also readiness to serve charges or emergency charges, and all discriminatory or preference charges of any and every kind whatever, be and the same are hereby prohibited.

Section 4. If said The Denver Union Water Company, or any of its officers, servants or agents, shall violate any of the provisions of this ordinance, the company or person so violating the same shall be deemed guilty of a misdemeanor, and, on conviction thereof, shall be punished by a fine or not less than one hundred dollars and not more than three hundred dollars.

Signed by me this 3rd day of March, A. D. 1914.

J. M. PERKINS, *Mayor.*

Attested by the undersigned with the corporate seal of the City and County of Denver.

No. 6274.

THE DENVER UNION WATER COMPANY, a Corporation, Complainant,
vs.
THE CITY AND COUNTY OF DENVER, a Corporation; J. M. PERKINS, Clair J. Pitcher, Alexander Nisbet, John B. Hunter, and Otto F. Thum, as Commissioners, Members of and Constituting the Council, of the City and County of Denver; J. M. Perkins, as Mayor and Commissioner of Social Welfare of the City and County of Denver; Clair J. Pitcher, as Commissioner of Finance of the City and County of Denver; Alexander Nisbet, as Commissioner of Safety of the City and County of Denver; John B. Hunter, as Commissioner of Improvements of the City and County of Denver; Otto F. Thum, as Commissioner of Property of the City and County of Denver; James F. Markey, as Auditor of the City and County of Denver; Armour C. Anderson, Edwin Van Cise and A. Lincoln Fellows, as Members of and Constituting the Public Utilities Commission of the City and County of Denver, Defendants.

Answer.

122 Come now the defendants in the above-entitled cause, by Isaac N. Stevens, George Q. Richmond, T. M. Patterson and George L. Nye, their attorneys, and for their joint and several answer to the bill of complaint in said cause, say:

First. That said bill of complaint does not state facts sufficient to constitute a cause of action within the jurisdiction of this court, in that it appears from said bill of complaint that the parties to this cause, complainant and defendant, are citizens and residents of the state of Colorado, the corporate defendants being duly organized and existing under and by virtue of the laws of the State of Colorado, and being citizens and residents of said state, and that it is not made further to appear by the facts alleged in said bill that there is a federal question involved herein.

Second. That the said bill of complaint does not state facts sufficient to entitle the complainant to the relief demanded, or to any relief whatever.

Wherefore, these defendants pray that said bill of complaint be dismissed, and for their costs in this behalf expended.

Second Defense.

Further answering, these defendants jointly and severally say:

First. Defendants admit that complainant is a corporation duly incorporated under the laws of the State of Colorado,
123 but as to whether complainant has fully complied with the laws of the State of Colorado, and is now authorized and empowered to acquire, construct, extend, own, maintain and operate water-works for and to engage in the business of supplying water to the City and County of Denver and its inhabitants for all or any uses and purposes, and to take tolls and rates therefor, and to acquire, own, maintain and operate such property as may be necessary or convenient, these defendants have not and cannot obtain sufficient knowledge or information upon which to base a belief. These defendants deny that complainant is entitled by right or otherwise to maintain and operate in the roads, streets, alleys and public places of the City and County of Denver, its pipes, mains, conduits and other apparatus constituting its plant and system for the supplying of water to and in said City and County of Denver; but these defendants admit that complainant was so authorized prior to the tenth day of April, 1910, and that since said date complainant has continued so to occupy and use said streets and public ways, but solely by sufferance and without right so to do.

Second. These defendants admit that the City and County of Denver is a municipal corporation, existing under and by virtue of Article XX of the Constitution of the State of Colorado; that J. M. Perkins, as Mayor and Commissioner of Social Welfare, Clair
124 J. Pitcher, as Commissioner of Finance, Alexander Nisbet, as Commissioner of Safety, John E. Hunter, as Commissioner of Improvements, and Otto F. Thum, as Commissioner of Property, are the commissioners, members of and constituting the council of the City and County of Denver; that James F. Markey is Auditor of said City and County, and that Armour C. Anderson, Edwin Van Cise and A. Lincoln Fellows, are members of and constitute the Public Utilities Commission of said City and County, and each and all of said individuals are residents and citizens of the City and County of Denver, State of Colorado.

Third. Defendants admit that this is a suit of a civil nature, in equity, involving more than the sum of five thousand dollars ($5,000.00), but deny that the controversy herein arises under the Constitution and laws of the United States, or that said Constitution and laws are in any manner involved.

Fourth. These defendants admit that complainant is a Colorado corporation, with an authorized capital as stated in the bill of complaint herein, and that said complainant is the successor in interest

of the various corporations in paragraph four of said bill of complaint alleged and set forth, and the owner of property theretofore owned by said companies, except that these defendants deny that the complainant or its predecessors in interest, or any of them, are
125 or were the owners of water rights or rights to the water supplied to the City and County of Denver and its inhabitants through the physical structures owned by said complainant or its predecessors in interest. These defendants admit the making, execution and delivery by the complainant of the mortgage or deed of trust set forth and described in paragraph four of complainant's bill of complaint, and the recording thereof, but as to whether all of the eight million dollars of bonds secured by said deed of trust are now outstanding in the hands of bona-fide purchasers for value, and as to whether since the organization of complainant, complainant has paid and distributed only the dividends set forth and described in paragraph four of complainant's complaint, or as to whether, with the exception of the dividends there described all of the net earnings and surplus of complainant earned and accumulated during its existence have been used and devoted to the purchasing and acquiring of additional property, to the extension, improvement and betterment of the water system owned by complainant and used for supplying the City and County of Denver and its inhabitants with water, and for the protection and preservation of said properties and the business of complainant, these defendants have not and cannot obtain sufficient knowledge or information upon which to base a belief.

Fifth. These defendants admit that the City and County of Den-
ver is a municipal corporation, having a charter which pro-
126 vides for a commission form of government, under which the powers and duties of the legislative, executive and administrative departments are exercised by a board of five commissioners, and that defendants Perkins, Pitcher, Nisbet, Hunter and Thum are the duly elected, qualified and acting Commissioners of said City and County of Denver; that James F. Markey is the duly elected, qualified and acting Auditor of said city and county; that Armour C. Anderson, Edwin Van Cise and A. Lincoln Fellows are the duly elected, qualified and acting members of the Public Utilities Commission, which commission derives its powers from and is now acting under Section 264-A of the Charter of the City and County of Denver. Defendants further admit that under Article XX of the Constitution of the State of Colorado, the City and County of Denver is the legal successor of the City of Denver and towns of Barnum, Colfax, Harmon, Highlands, South Denver, Argo, Berkley, Elyria, Globeville, Montclair and Valverde, and embraces within its exterior boundaries all of the territory formerly embraced in each of said municipalities, including approximately 37,920 acres.

Sixth. These defendants admit that in 1870 The Denver City Water Company began the construction of a water-works system to supply the City of Denver and its inhabitants with water; that prior to the organization of The Denver Union Water Company in 1894
and the acquirement by it of the properties of its grantor
127 companies, said companies had constructed water systems for supplying the City and County of Denver with water; that

upon the organization of complainant in 1894 it united said water systems into one system, which since said times has been operated as a unit, and has been and is now the principal source of actual supply of water for all purposes for the City and County of Denver and its inhabitants; but these defendants deny that said system is the only source from which the said City and County of Denver and its inhabitants can be supplied with water. These defendants admit that in 1870 the City of Denver had a population of approximately 4,759 persons, and that the population has increased substantially as in complainant's bill of complaint alleged; that the commercial, financial and material growth of said city has increased correspondingly to its increase in population, and that the demands on the complainant and its grantor companies likewise increased in connection with the supplying of water to said City and County of Denver and its inhabitants. These defendants admit that complainant and its grantor companies from time to time since 1870 have added to their properties and expanded the said water system, and have expended large sums of money thereon. These defendants deny that at the present time and for some years last past the properties of complainant constitute an efficient water supply for the City and
128 County of Denver and its inhabitants; and as to whether said system embraces every element of structure and equipment found in any water system, together with additional important elements necessitated by peculiar local conditions, as alleged, these defendants have not and cannot obtain sufficient knowledge or information upon which to base a belief. These defendants admit that complainant, or its grantors, have constructed large reservoirs, capable of impounding sufficient water to meet the present requirements of the City and County of Denver, but these defendants deny that said reservoirs are sufficient to meet the demands or requirements of the City and County of Denver and its inhabitants, reasonable or otherwise, in the immediate future without replenishing and without aid from other sources. These defendants admit that complainant and its grantors have in various ways acquired certain water rights and rights for the carriage of water by appropriation and purchase; that some of said rights were early rights to water that can be advantageously used for a water supply for the City and County of Denver; but these defendants deny that the complainant or its grantors have ever at any time, by use or consumption, initiated, held or owned any of the water or water rights claimed by complainant, and allege that at all times complainant has served but as a carrier of the water supply of the City and County of Denver and its inhabitants and that the right to and ownership of all water rights and
129 rights to water carried through the system and pipes of complainant company have belonged to and are now vested in the City and County of Denver and its inhabitants. These defendants deny that by the operations and efforts of complainant there has been developed a water supply ample for all the needs and requirements of the City and County of Denver and its inhabitants, with rights perfected for use all the year around instead of for the crop growing season, as in case of irrigation rights; deny that such rights are

such magnitude as to control during a considerable portion of every year all the water flowing in the streams above Denver in the non-irrigating season, but these defendants allege that all efforts of complainant and its grantors and predecessors in interest would have proved futile and of no avail except for the use and consumption of the water flowing in the pipes and system of complainant by the City and County of Denver and its inhabitants. These defendants admit that the supply of water carried through the system of complainant is diverted at six separate and distinct locations on the South Platte River, Bear Creek and Cherry Creek, at distances ranging from three to forty-eight miles from the city, and that the principal physical properties of the water system referred to are as in paragraph six of complainant's bill of complaint described in a general way. These defendants admit that the city and county of Denver is located
130 in a semi-arid region at the eastern base of the Rocky Mountains, and that it is more or less dependent for its water supply upon the small mountain streams which flow through or near it, but defendants deny that the City and County of Denver and its inhabitants are solely dependent upon such streams as a source of water supply. These defendants admit that the agricultural regions surrounding and adjacent to said City and County are more or less dependent upon the water from said mountain streams as a source of irrigation and in connection with the raising of crops, and that as the population of the City and County of Denver has increased and the population of the surrounding and adjacent country has increased, the demand for water has correspondingly increased, until a considerable portion of the water flowing eastward from the Rocky Mountains in and around the City of Denver has been appropriated and has been and is being used for domestic and irrigation purposes; but these defendants deny that all of such water has been so appropriated, and deny that the City and County of Denver has not now and never has had any source of water supply for itself and its inhabitants, but allege that the said City and County now owns, and for many years last past has owned, a considerable water supply, capable of supplying a substantial part if not all of the demands of said City and County and its inhabitants for water; but these defendants
131 admit that said City and County has not at the present time any plant or system capable of distributing said water to said city and county and its inhabitants, but allege that said city and county and its inhabitants have determined and are proceeding as speedily as may be to construct a water plant and system capable of distributing said water and other waters to and adequately supplying said City and County of Denver and its inhabitants with water.

Seventh. Defendants admit that since the formation of complainant in 1894 much of the property acquired from its grantor companies, together with additions, extensions, betterments and improvements thereto, has been devoted to the necessary and actual use of supplying defendant the City and County of Denver and its inhabitants with water for all purposes, and that complainant has constantly and from time to time added to its properties and water system, but deny that complainant has at all times added to its properties and

water system as the needs of defendant the City and County of Denver and its inhabitants have manifested themselves, and deny that all of complainant's property has been or is devoted solely to the actual and necessary use of supplying the defendant City and County of Denver and its inhabitants with water. These defendants admit that complainant acquired from The Denver Water Company a certain franchise known as Ordinance No. 44 of 1890, which entitled
132 said Denver Water Company and its assigns to occupy the streets and public ways of the City of Denver to supply said city and its inhabitants with water, and to charge for such services a certain schedule of rates set forth in said ordinance; but these defendants deny that the charges permitted by said ordinance, or made or collected by complainant or its predecessors in interest, were for the water furnished, but on the contrary these defendants allege that such charges were permitted, were made, and paid by the defendant City and County of Denver and its inhabitants for the service rendered by complainant and its predecessors in interest as carriers or conveyors of the water theretofore, then, and ever since owned by said City and County of Denver and its inhabitants, as the ultimate consumers and users thereof. These defendants admit that the charges fixed by Ordinance No. 44 of 1890 were continued until April 10th, 1910, and until, in a suit in the circuit court of the United States for the District of Colorado, entitled The New York Trust Company against The City and County of Denver, et al., No. 5572 in equity, all rights and privileges of complainant under said ordinance were held to have terminated.

Eighth. These defendants admit that Schedule "A" as fixed in said Ordinance No. 44 of 1890 was the basis of rates charged and collected for said water service from the time of its enactment
133 until 1895, when the schedule known as the Leaflet Schedule, making a horizontal reduction in said rates, was put into effect, which said Leaflet Schedule was in effect from 1895 to and including the year 1913, except for the years 1898 to 1907, during which time rates in excess thereof were charged and collected by complainant claiming to act under and by virtue of the authority of a certain decree entered in the District Court of the State of Colorado for the Second Judicial District, in a cause entitled The City of Denver against The Denver Union Water Company, being cause No. 26251 in said court. Defendants admit that Ordinance No. 44 of 1890 provided certain charges for hydrants, and that complainant has collected and the City and County of Denver has paid for the use of such hydrants for the years 1891 to 1913, inclusive, as in said ordinance provided; and these defendants admit that the payments for 1910, 1911, 1912, 1913 and 1914 have been accepted by complainant with an attempted reservation upon the part of complainant of a right to claim an additional rate per hydrant; but these defendants deny that said attempted reservation was in any manner or at all effectual, and allege that complainant has at all times and in all years been fully paid by the City and County of Denver for all five hydrants and the water service thereto rendered by the complainant.

Ninth. These defendants admit that water is a commodity hav-

ing an ascertained value in the City and County of Denver,
134 and State of Colorado, and that such value increases as uses therefor increase, and admit that for many years it has been necessary that the needs of defendant City and County of Denver for water should be anticipated, and that the supply of water capable of being furnished to said City and County of Denver and its inhabitants should be several years in advance of the actual present need, and that without such anticipation future growth of the City and County of Denver would be impeded; but these defendants deny that such need has been anticipated or provided for by complainant. Defendants admit that at certain periods of the year all of the natural flow of the streams supplying water to the City and County of Denver is not sufficient to supply the daily consumption of water in said City and County of Denver; but these defendants deny that such deficiency is equal to one-half the daily consumption of water in said City and County. These defendants admit that it is and has been and now is essential, in order to supply the City and County of Denver and its inhabitants with water, and protect the health and safety of said inhabitants, that large storage reservoirs should be built and maintained on the headwaters of the streams above Denver, and admit that complainant has constructed, or caused to be constructed, some such reservoirs, but these defendants deny that the reservoirs constructed by complainant are adequate or sufficient
135 for the needs of the City and County of Denver and its inhabitants, and deny that the reservoirs constructed by complainant cannot now be duplicated upon the streams above said city and county. These defendants admit the incorporation of The South Platte Canal and Reservoir Company, and that complainant owns all of the capital stock of said company. These defendants admit that The South Platte Canal and Reservoir Company, acting under the control of complainant, and by the expenditure of money obtained and furnished by complainant, constructed a dam and created a reservoir known and designated as the Cheesman Lake and Dam, on the south fork of the South Platte River, approximately forty-eight miles from the City and County of Denver, and admit that said Lake and dam has been used and is necessary to be used until the construction of another reservoir or reservoirs to take its place as a storage reservoir or reservoirs to impound and store water for supplying the city and county of Denver and its inhabitants with water; but as to the amount of water now contained in said lake and dam, and whether the amount thereof is sufficient to meet the demands of the city and county of Denver and its inhabitants, to permit of its future growth, and protect the health and safety of said city and its inhabitants, these defendants have not and cannot obtain sufficient knowledge or information upon which to base
136 a belief. These defendants admit the construction of Cheesman Lake and Dam at the point and substantially in the manner alleged and set forth in complainant's bill of complaint, and that the area of said reservoir, and the acres included therein and surrounding said reservoir, controlled by complainant, are substantially as alleged in complainant's bill of complaint. These defend-

ants admit that The South Platte Canal and Reservoir Company authorized and issued $4,000,000.00 of bonds, secured by a trust deed running to Morton Trust Company of New York, and covering all of its property acquired and to be acquired, and that complainant guaranteed the payment of both principal and interest of said bonds; but as to whether or not said bonds have heretofore been issued and sold, and in good faith purchased, and are now outstanding in the hands of purchasers for value, these defendants have not and cannot obtain sufficient knowledge or information upon which to base a belief. These defendants admit that on May 1st, 1903, The South Platte Canal and Reservoir Company entered into an agreement of lease with the complainant substantially as in paragraph nine of complainant's bill of complaint set forth, but these defendants deny that then or now The South Platte Canal and Reservoir Company owned any of the waters carried through its system or the system of complainant. These defendants admit that the property of

137 The South Platte Canal and Reservoir Company leased to complainant, except the water attempted to be leased to complainant, has been ever since the date of said lease in the possession and control of complainant, and that the same is an essential and integral part of the water-works system of complainant devoted to supplying the City and County of Denver and its inhabitants with water, and that under said lease complainant was obligated to operate and maintain the properties by it leased, and to pay all operating costs, taxes and interest on bonds of said South Platte Canal and Reservoir Company. Defendants admit that the properties of the South Platte Canal and Reservoir Company are operated and used as a unit with complainant's property, but as to whether the obligations contained in said lease have been performed by complainant these defendants have not and cannot obtain sufficient knowledge or information upon which to base a belief.

Tenth. These defendants admit that in October, 1907, Ordinance No. 163 of the series of 1907 was enacted, approved and published as an ordinance of the City and County of Denver, and these defendants admit that thereafter appraisers were appointed substantially as in complainant's bill of complaint alleged, and that said appraisers proceeded to appraise said property, and thereafter made a report of their said appraisement substantially as alleged and set forth in complainant's complaint.

Eleventh. These defendants say that as to the allegations

138 in paragraph eleven of complainant's bill of complaint concerning the expenditures of complainant for betterments, improvements, extensions and additions to its properties and water system since October 20th, 1907, these defendants have not and cannot obtain sufficient knowledge or information upon which to base a belief. Defendants further say that as to the allegation that the expenditures made and claimed to have been made by complainant represented the actual and reasonable cost and value of the betterments, improvements, extensions and additions made, these defendants have not and cannot obtain sufficient knowledge or information upon which to base a belief. These defendants admit

that such betterments, improvements, extensions and additions as have been made were necessary and proper, but these defendants allege that the water system and plant of complainant is still inadequate to furnish the proper, sufficient and necessary water supply to the City and County of Denver and its inhabitants.

Twelfth. These defendants admit that prior to April 10th, pursuant to and in accordance with the provisions of Article XX of the Constitution of the State of Colorado and the Charter of the City and County of Denver, complainant prepared and caused to be submitted to the tax-paying electors of the City and County of Denver, at the general election held May 17th, 1910, a proposed franchise and cont-act to be entered into between complainant
139 and defendant the City and County of Denver for a continuance of the relation between complainant and the city and county of Denver and the supplying of water by complainant to the City and County of Denver and its inhabitants, which said proposed ordinance and franchise was defeated and rejected by defendant the City and County of Denver at said election; but these defendants deny that said ordinance provided, upon reasonable and fair terms, for a continuance of said relation between complainant and the City and County of Denver, and allege that the terms of said ordinance proposed by complainant were unreasonable, unfair, unjust and oppressive. These defendants admit that at the same election there was submitted to the voters a proposition for defendant the City and County of Denver to purchase the water system and property of complainant upon a new appraisement, which proposition was likewise defeated and rejected. These defendants admit that at the same election, and subsequent to the appraisement of $14,400,000.00 fixed by said appraisers, there was initiated and submitted to the voters of defendant the City and County of Denver Section 264-A of the Charter, creating a Public Utilities Commission, composed of defendants Anderson, Van Cise and Fellows, and providing for an offer of $7,000,000.00 for the property of complainant, and that in case such offer should not be accepted steps should be taken to construct and build a complete competitive
140 water system at a cost of not to exceed $8,000,000.00, and that said charter amendment known as Section 264-A was adopted at said election.

Defendants admit that at a special election held in the City and County of Denver on February 17th, 1914, there was submitted to the electors and tax-paying electors of defendant city a contract to purchase substantially as in complainant's bill of complaint set forth, but these defendants deny that the profit-sharing basis proposed in said contract would have yielded to complainant far less than a reasonable return upon the reasonable and actual value of its properties, and defendants admit that said proposed contract to purchase was rejected and defeated at said election. These defendants admit that at various times since April 10th, 1910, complainant has offered to sell its properties and water system, together with betterments, extensions, improvements and additions thereto, at a price to be fixed by appraisement, but these defendants say that

as to the defendants constituting the Public Utilities Commission they have at all times been without right or authority to consider the purchase of complainant's water system except upon the terms fixed by the provisions of Section 264-A which created said Commission, and as to the defendant the City and County of Denver these defendants say that each and every proposition properly presented by complainant has been in due course submitted to
141 the electors of the City and County of Denver as required by law, and that said electors have rejected such propositions, as they had a perfect right to do. These defendants admit that they have made no attempt to acquire the properties and water system of complainant, except the attempt and offer authorized by Section 264-A and that they have made no attempt to grant for a definite time a contract or franchise to complainant for further supplying water to the City and County of Denver and its inhabitants, and these defendants allege and say that the offer authorized by the terms of Section 264-A was submitted to the complainant by the Public Utilities Commission, and was by complainant refused; that various propositions acceptable to complainant have been submitted to the qualified electors of the City and County of Denver since April 10th, 1910, and each of such propositions so submitted have been rejected by said electors, and that these defendants individually and collectively have not been and are not now under any obligation, legal or equitable, to grant to complainant a contract or franchise for any purpose. These defendants admit that complainant has since April 10th, 1910, continued to serve the City and County of Denver and its inhabitants with water, but these defendants allege that complainant has at all times since April 10th, 1910, charged and collected for the water service rendered by it at least the amount theretofore charged and collected, and allege that complainant has received and is receiving all
142 and more than that which as a carrier of water it is entitled to receive for the services which it has rendered and is rendering. These defendants deny that the inhabitants of the City and County of Denver have no source of water supply for themselves other than the supply furnished through complainant's system, which supply of water these defendants allege is the property of the City and County of Denver and its inhabitants by virtue of their appropriation, long continued use, and consumption thereof, and these defendant deny that the City and County of Denver *has* no plans or specifications for the construction of a complete and independent water system as proposed under Section 264-A of the Charter, and deny that they have no water or water rights even partially adequate for the purpose of supplying the City and County of Denver and its inhabitants with water. These defendants deny that a complete and independent water system for the City and County of Denver cannot be constructed in less than seven years, but these defendants admit that during the construction of a new system the City and County of Denver and its inhabitants will be dependent for the delivery of their water supply upon the water system of complainant. Defendants admit that every offer of com-

plainant to sell its properties and water system to the City and County of Denver has by said city and county been rejected, and that every suggestion of complainant for a contract or fran-
143 chise has likewise been rejected; but these defendants deny that such offers and suggestions have been fair and reasonable in terms, and allege that each and every such offer and suggestion has been unfair, unreasonable and at excessive prices, and upon terms wholly unsatisfactory to the electors of the City and County of Denver, with whom lies the right for final determination of such questions. These defendants deny that they have threatened or are threatening to destroy all or any part of the property of complainant and its value, or to require complainant to continue to devote its property and water system to supplying defendant the City and County of Denver and its inhabitants with water at rates and charges and upon terms which will not yield a fair and reasonable return upon the actual value of the property of complainant, and allege that the rates and charges fixed by ordinance of the City and County of Denver, duly passed and adopted, known as Ordinance No. 26, 1914, are fair, reasonable, just, and will produce for complainant a fair, reasonable and adequate return upon the capital actually invested by complainant in its water system and carrying service.

Thirteen. Defendants admit that water rates and charges under the leaflet schedule and the schedules prior thereto have been payable in advance semi-annually on the first days of May and No-
144 vember, and that the fiscal year of complainant begins on the first day of November in each year. Defendants admit that complainant has been and is serving approximately 44,280 water consumers, who receive their entire supply through complainant's system, and that in the year May 1st, 1914, to May 1st, 1915, the number of water consumers will be approximately the same. As to the allegations in paragraph thirteen of complainant's bill of complaint concerning the financial operations of complainant, its gross earnings, operating expenses, taxes, net income, etc., as therein set forth, and as to the allowances made or which should be made for depreciation, obsolescence or unusual contingencies, these defendants have not and cannot obtain sufficient knowledge or information upon which to base a belief.

Fourteenth. These defendants admit that the quantities of water furnished and delivered through complainant's system in the years 1908 to 1913, inclusive, were substantially as in paragraph fourteen of complainant's bill of complaint set forth, and that the amount of water to be consumed during the year May 1st, 1914, to May 1st, 1915, and supplied through complainant's system, will be approximately as in said paragraph set forth.

Fifteenth. These defendants deny that neither the defendant the City and County of Denver nor the Public Utilities Commission prior to August 11th, 1913, made any attempt to investigate
145 or value the properties and water system of complainant, but admit that no such attempt was made through a commission of engineers until on or about the 11th day of August, 1913. De-

fendants admit that on August 11th, 1913, defendants the City and County of Denver and the Public Utilities Commission appointed A. Lincoln Fellows, C. P. Allen and Edmond C. Van Diest as a commission to inspect, examine and report upon the properties and water system of complainant, and that said engineers were engaged upon their report until January 14th, 1914, at which time they presented a report, extracts from which report are as set forth in paragraph fifteen of complainant's bill of complaint; but these defendants deny that said report was not submitted until after said Public Utilities Commission had requested said three engineers to eliminate from their said report certain statements and valuations more favorable to complainant and its properties than those contained in said report as filed, and deny that any such request was made by said commission at any time or at all. These defendants admit that water and water rights claimed by complainant and used in supplying defendant the City and County of Denver and its inhabitants with water were omitted by said engineers in their appraisement, and allege that said water and water rights were so omitted because said water and water rights belonging to the City and County of Denver and its inhabitants as the users and consumers thereof. These
146 defendants deny that there is any "going concern value" which is an integral and necessary part of the unit value of the water system of complainant amounting to not less than fifteen per cent of the total value of the physical properties of complainant and the water rights claimed by it, or amounting to any sum or value whatever which forms any part or portion of the unit value of complainant's system, but admit that no "going concern value" was included by said engineers in said report. Defendants admit that in the investigation, inspection and work of said engineers complainant afforded the said engineers every reasonable opportunity for inspection and examination of its records and data, and that the inspection and examination made by said engineers was ex parte; but these defendants deny that if opportunity had been afforded to complainant to present testimony, data, information or argument on its behalf the valuation placed upon the water system of complainant by said engineers would have approximated the appraised value fixed by the appraisers appointed by the complainant *had* the City and County of Denver in 1907, and allege that said engineers by reason of the opportunity afforded them by complainant and all knowledge or information bearing upon the subject under their investigation, and that the report made by them was based upon such a knowledge and information. That as to the allegations in paragraph fifteen of complainant's bill of complaint concerning its employment of
147 George G. Anderson and Leonard P. Metcalf as engineers, its reasons therefor, and the result of the investigation and appraisement of such engineers, these defendants have not and cannot obtain sufficient knowledge or information upon which to base a belief.

Sixteenth. These defendants admit the preparation of a bill for an ordinance and the passage of Ordinance No. 26 of the Series of 1914, a copy of which is attached to complainant's bill of complaint as

Exhibit "A", and that said bill for an ordinance was prepared and said ordinance enacted without consultation or conference with complainant; but these defendants deny that said ordinance was passed without notice to complainant or without opportunity afforded to be heard in reference to the matters therein contained, and the effect thereof on the income and properties of complainant, and allege that said ordinance was regularly initiated by the people under the terms of the Charter of the City and County of Denver and subsequently duly and regularly adopted by the Council of the City and County of Denver and regularly and duly published, with every opportunity allowed or provided by law for any party in interest, including complainant, to protest or contest the same. These defendants deny that neither the City and County of Denver, the Public Utilities Commission or any member thereof, or the Council of the City and County of Denver, or any member thereof, attempted
148 prior to the enactment of said ordinance to investigate the fairness or justice of the rates therein provided, or the effect thereof upon the income or properties of complainant, and allege that each and all of said defendants duly and fully investigated and considered the rates therein provided and the effect thereof, and after full and due consideration determined that said rates were reasonable, fair and just, and these defendants allege that the rates and terms of said ordinance are fair, reasonable and just, and provide a reasonable and adequate return to complainant upon the capital actually invested by it in its carrying system. These defendants deny that said ordinance was conceived, prepared, drafted and enacted without reference to the fairness of the rates therein prescribed, or the effect upon the properties and income of complainant, but for the purpose of crippling and hampering complainant in the operation of its water system, and to depreciate the earning capacity and value of the properties and water system of complainant, in order to enable the defendant the City and County of Denver and said Public Utilities Commission to purchase and acquire the properties of complainant at less than their fair, actual, present value, or for the purpose of in any manner crippling and hampering complainant in the operation of its water system, or in any manner or at all, or to depreciate the legitimate earning capacity and value of the properties and
149 water system of complainant, or to in any manner depreciate the legitimate value of such properties and water system to enable the defendants the City and County of Denver and the Public Utilities Commission to purchase and acquire the properties of complainant at less than their fair, actual, present value, or to enable them to purchase said properties at any price or at all. These defendants admit that the schedule of rates set forth in said exhibit "A" follows generally the items and form of Schedule "A" and the Leaflet Schedule, and that the declared purpose in the enactment of said Exhibit "A" was to reduce the rates under said Leaflet Schedule twenty per cent horizontally.

Seventeenth. These defendants deny that Exhibit "A" reduces the charges to be made by complainant and the gross earnings to be derived thereunder in excess of twenty-one per cent, but admit that

Exhibit "A" requires that certain water service shall be supplied by complainant to defendant the City and County of Denver without charge, and allege that such water service is reasonable, and constitutes a reasonable, just and fair charge upon the complainant for its temporary use and occupancy of the streets and public ways of the City and County of Denver, used and to be used by it in serving water to the City and County of Denver and its inhabitants, for which complainant will receive large revenues. Defendants deny that $18.00 per year for every fire hydrant is less than the reasonable and
150 fair charge for hydrant service, and allege that said sum of $18.00 per year is a reasonable and fair charge and a just and a reasonable compensation to complainant for fire hydrant service.

Eighteenth. Defendants deny that if Exhibit "A" is enforced against complainant the gross earnings of complainant for the year May 1st, 1914, to May 1st, 1915, will be more than $289,215.00 less than for the fiscal year 1913, and that said sum will likewise constitute a reduction in net income of complainant. That as to the allegation that under Exhibit "A" the result of the operation of the properties of complainant for the year May 1st, 1914, to May 1st, 1915, will be as in paragraph eighteen of complainant's bill of complaint alleged, these defendants have not and cannot obtain sufficient knowledge or information upon which to base a belief; but these defendants deny that the sum of $170,000.00 per year is a reasonable allowance for actual depreciation and obsolescence upon the water system of complainant. Defendants deny that under Exhibit "A" and the rates, charges and terms fixed therein, if the same is enforced, the net earnings of complainant for the year May 1st, 1914 to May 1st, 1915, will return to the complainant less than 2.88 per cent upon the present actual value of the properties and water system of complainant used in supplying the City and County of Denver and its inhabitants with water for all purposes during said time.
151 and defendants allege that the net earnings to complainant under Exhibit "A" upon the present actual value of the properties and water system of complainant will be far in excess of said percentage of 2.88 per cent.

Nineteenth. Defendants admit that they have declared and are declaring their purpose of enforcing the terms and provisions of Exhibit "A", and that defendants and the inhabitants of the City and County of Denver will, unless restrained and prevented by order of court, refuse to pay to complainant any charges for water other than those fixed in said Exhibit "A", and allege that said Exhibit "A" is in all respects a valid subsisting ordinance, duly and regularly passed by the properly constituted authorities, and governs and fixes the rates and charges which complainant is entitled to demand and receive for the water service therein referred to and provided for.

Twentieth. Defendants admit that the fifth and fourteenth amendments to the Constitution of the United States provide substantially as in paragraph twenty of complainants' bill of complaint alleged and set forth; but these defendants deny that this pending case is a cause arising in equity under the Constitution of the United States, and

deny that the judicial power of this Honorable Court extends to and embraces the issues made and attempted to be made in this
152 cause, and deny that the issues set forth and attempted to be set forth in complainant's bill of complaint involve a federal question under the Constitution of the United States. These defendants deny that by reason of the acts, facts and things alleged in complainant's bill of complaint, or by reason of any acts, facts or things, the rates provided in Exhibit "A" are unreasonable, unjust, fraudulent, confiscatory, ambiguous, uncertain and unintelligible, and if enforced will compel complainant to conduct its business and operations without fair remuneration, and as to certain portions of said business and operations, a supplying of water without any remuneration or compensation. Defendants deny that said rates and terms as provided in Exhibit "A" are violative of and prohibited by each and all of the said provisions of the Constitution of the United States, and deny that by reason of and under said provisions, or in any manner, or at all, said rates and terms are null and void. Defendants deny that under Exhibit "A" complainant will be compelled to furnish water to defendant the City and County of Denver and its inhabitants at less than the fair, reasonable and just value of the services rendered, and deny that by the enforcement of the rates and terms of Exhibit "A", or in any manner, or at all, complainant will be deprived of property without due process of law, and deny that complainant will be deprived of property without any process
153 of law, in violation of the provisions of the Constitution of the United States, or in any manner, or at all, and deny that the property of complainant will be taken for public use without just compensation, and in some instances without any compensation, or in any manner, or at all, taken without just, fair and adequate compensation, and deny that by and through the enforcement of said Exhibit "A", or in any manner, or at all, the privileges and immunities of complainant will be abridged and the equal protection of the law denied to it, in violation of the provisions of the Constitution of the United States, or in any manner, or at all, denied to complainant. Defendants deny that the rates and terms fixed by Exhibit "A" were or are wholly void, null, unjust, unreasonable, fraudulent and unconstitutional, or in any manner void, null, unjust, unreasonable, fraudulent and unconstitutional under the provisions of the Constitution of the United States, or in any manner, or at all, and deny that the same are oppressive, confiscatory, ambiguous, uncertain and unintelligible, and do not permit of or provide for a just or fair or reasonable compensation for water service to be supplied from May 1st, 1914, to May 1st, 1915, to the City and County of Denver and its inhabitants, and allege that the rates and terms of Exhibit "A" are in all respects fair, just, reasonable, and provide full, adequate and sufficient compensation to complainant for services
154 rendered and to be rendered, as in said bill of complaint set forth and by said Exhibit "A" required and fixed.

Twenty-first. Defendants deny that Section two of Exhibit "A" was and is unreasonable, unjust and unconstitutional under the provisions of the Constitution of the United States in complainant's

bill of complaint referred to. Deny that said section is confiscatory and greatly inadequate as to compensation to complainant for the services therein contemplated. Deny that the services in said Section two contemplated for hydrant rentals, excluding any service as to fire service and protection, are reasonably, fairly and justly worth the sum of more than $25.00 per hydrant per year, and allege that said services are not reasonably, fairly and justly worth more than the sum of $18.00 per hydrant per year. Defendants deny that the value of complainant's property and water system actually in use for the part of its service referred to in Section two of Exhibit "A" over and above and in excess of the value of the property of complainant required and necessary for all other uses of water supplied by it, has been and will, during the year May 1st, 1914, to May 1st, 1915, be largely or at all in excess of the principal sum which at six per cent per annum would produce the rate or revenue of $25.00 per year per hydrant. Defendants deny that the gross income received by complainant for the year ending
155 May 1st, 1914, did not yield a fair interest or return upon the actual value of the property actually and necessarily used in supplying the City and County of Denver and its inhabitants with water after deducting operating expenses, taxes, depreciation, obsolescence and other deductions to which complainant is entitled, and allege that after all reasonable and proper deductions and allowances the gross income received by complainant for the year ending May 1st, 1914, yielded a fair interest and a reasonable, fair and just return upon the actual value of complainant's property so employed.

Twenty-second. Defendants admit that included in the water system of complainant are certain physical properties which are by their nature and the uses to which they are subject constantly undergoing depreciation, and admit that complainant is entitled to have its property devoted to the public use of supplying the City and County of Denver and its inhabitants with water remain unimpaired in value, so far as its actual use in supplying the City and County of Denver and its inhabitants with water is concerned, and to receive for the services rendered in supplying such water a reasonable return upon the value of the property devoted to such use, and a sufficient amount to protect said property against depreciation and other impairments of value in connection with such use
156 and such water service; but these defendants deny that complainant is entitled to receive compensation of any character for the water supplied to the City and County of Denver and its inhabitants, and allege that said water is the property of said City and County of Denver and its inhabitants, and complainant is entitled to compensation only for its services as carrier in delivering such water. As to the allegation that it is now a common practice for companies of the character of complainant to make an annual allowance for insurance against destruction by fire or other casualty, for depreciation, aging and wearing out, and obsolescence of plant, and to provide a fund for replacing said property when destroyed or worn out, and when it has become obsolete, these defendants have

not and cannot obtain sufficient knowledge or information upon which to base a belief. Defendants admit that there is continually in progress in all water systems a waste and depreciation due to use, ravages of time and action of the elements, but defendants deny that a portion only of such waste and depreciation can be offset by ordinary and current repairs, and allege that in a properly constructed system all such waste and depreciation can be and is offset by ordinary and current repairs. Defendants admit that waste, depreciation and replacement enter into the cost of furnishing, supplying and delivering water. Defendants deny that to maintain a water system and to maintain the properties and water system of
157 complainant it is necessary to provide for, (*a*) ordinary depreciation, and (*b*) obsolescence of portions of the plant, and allege that if ordinary depreciation is properly cared for and protected against, obsolescence such as that described and alleged in paragraph twenty-two of complainant's bill of complaint will not arise. As to the allegation that the practice of making an annual allowance for obsolescence as well as depreciation has become so well established and so necessary that public service commissions in many states in the instructions which they issue provide for a separate statement of such items, and as to whether the term "obsolescence" is now and has been for many years last past generally accepted by accountants as the proper term as indicating the loss resulting from discarded property, plant and machinery before it is worn out, and the substitution therefor of improved property, plant and machinery, these defendants have not and cannot obtain sufficient knowledge or information upon which to base a belief. These defendants deny that obsolescence as distinguished from depreciation constitutes an annual expense to complainant in supplying water to the City and County of Denver and its inhabitants. These defendants deny that complainant is entitled to an allowance to cover extraordinary casualties and contingencies such as fire and flood as an annual or other periodical allowance, to be con-
158 sidered as an element of depreciation, and defendants deny that to cover, provide for and compensate complainant for depreciation, obsolescence and other deductions, as alleged in complainant's complaint, or at all, complainant will be entitled during the year May 1st, 1914, to May 1st, 1915, to an allowance of $170,000.00, and deny that the sum of $170,000.00 is a reasonable amount to provide for such items, and allege that a reasonable and proper allowance to complainant for the items referred to does not exceed the sum of $50,000.00 per year.

Twenty-third. These defendants deny that it is essential, meet, right, proper and necessary to the rights of complainant, present and future, that this court by decree determine the actual and reasonable value of the property and water system of complainant now devoted to and which will be used from May 1st, 1914, to May 1st, 1915, in the supplying of water and the rendering of service in connection therewith to the City and County of Denver and its inhabitants, and deny that if it be determined to be at all proper or necessary that this court should by decree in this cause determine

the reasonable value of the water system of complainant, there should be included or taken into consideration in such determination the alleged going concern or assembled value of said water system, or any allowance whatever for obsolescence or replacement of property destroyed by extraordinary casualty, and deny that this
159 court should in any manner take into consideration in its determination any question of income based upon going concern or assembled valuation, or based upon an allowance for obsolescence or extraordinary casualty; and these defendants, without admitting that any such determination should be made, allege that if it be made the court is only entitled to take into consideration the actual and reasonable value of complainant's water system and the fair value of services rendered by complainant in furnishing to the City and County of Denver and its inhabitants the water belonging to them through the physical system of complainant.

Twenty-fourth. Defendants deny that neither the Council of the City and County of Denver nor any members thereof who passed or acted upon Exhibit "A" had any right, power or authority whatsoever to consider, enact or approve said Exhibit "A" under Article XX of the Constitution of the State of Colorado or the Charter of defendant the City and County of Denver, and deny that each and every act of said Council in reference to said Exhibit "A" is and was at all times of no effect whatsoever, and allege that said Council and the members thereof were fully authorized and empowered under said Article XX of the Constitution of the State of Colorado, and under the Charter of the City and County of Denver to do and perform each and every act done and performed by them in
160 respect to said Exhibit "A." These defendants deny that Exhibit "A" is null and void and of no force or effect whatsoever, because not legally passed or adopted by the Council, or for any other reason, or at all, and allege that said Exhibit "A" is a duly passed, adopted, published and effective ordinance in all respects. These defendants deny that neither the Council of the City and County of Denver nor the members thereof had any right, power or authority to fix or attempt to fix the charges for services rendered and to be rendered by the complainant, and allege that said council was at all times so empowered and acted strictly in accordance with its power and authority in the passage and adoption of said Exhibit "A."

Twenty-fifth. Defendants admit that taxes heretofore paid by complainant have been taxes duly and legally assessed against the property of complainant, consisting of its water system and physical plant, but as to whether the expenditures for operations heretofore made by complainant as in complainant's bill of complaint alleged and set forth are the actual, necessary and reasonable charges incurred in the operation of the properties and water system of complainant for the purpose of supplying the City and County of Denver and its inhabitants with water, these defendants have not and cannot obtain sufficient knowledge or information upon which to base a

belief; but these defendants allege that they are informed and
161 believe, and charge the fact to be, that complainant has made large and extensive expenditures of money in its efforts to force its water system and plant upon the City and County of Denver at a price largely in excess of its actual and reasonable value.

Twenty-sixth. These defendants deny that under Section 4 of Exhibit "A" defendants and each of them are threatening to arrest and fine complainant and any of its officers who may attempt to collect rates other than those set forth in said Exhibit "A", or to do anything contrary to the provisions of Exhibit "A"; but these defendants admit that unless restrained by this Honorable Court they will, in a legal and proper manner, and with orderly procedure, enforce the terms and provisions of said Exhibit "A" as an ordinance of the City and County of Denver. These defendants deny that the enforcement of Section 4 of Exhibit "A" will result in a denial to complainant of the equal protection of the laws, and render its property liable to be taken without due process of law, because complainant is only allowed a hearing on the claim of the unconstitutionality of Exhibit "A" and the provisions thereof, at the risk, if mistaken, of being subjected to enormous, unusual and confiscatory penalties, resulting in the possible confiscation of a large part of its property, or for any reason, or at all. Defendants admit that the inhabitants of the City and County of Denver will make Exhibit "A"
162 and the rates therein provided the excuse and justification by them as water consumers for refusing to pay any charge in excess thereof made by complainant, and allege that the rates fixed by Exhibit "A" are fair, reasonable and just, and all that the inhabitants of the City and County of Denver ought to pay for the services rendered by complainant in supplying them with water. These defendants deny that in manner alleged, or at all, complainant will be unable to effect collection of fair, reasonable and just water rates and charges. Defendants deny that unless defendants and the inhabitants of the City and County of Denver be by the orders and decrees of this court restrained from executing and enforcing Exhibit "A" complainant will suffer great and irreparable injury, or any injury, and deny that a multiplicity of suits will result. Defendants deny that complainant has no adequate remedy at law for the redress of injuries which it claims will be inflicted upon it and its property and officers by the enforcement or the attempt to enforce Exhibit "A", and deny that any injury will be inflicted upon complainant by the enforcement of said Exhibit "A". These defendants deny that the interposition of the power of a court of equity is necessary in any manner, or at all, to protect the alleged rights of complainant and complainant's property, or any rights or property of complainant in any manner, or at all.

163 Wherefore, having fully answered, these defendants pray that complainant take nothing by its bill of complaint herein, but that said complaint be dismissed, and for their costs in this behalf expended.

Third Defense.

These defendants, now and at all times hereafter saving to themselves all and all manner of benefit of exception or otherwise that can or may be had or taken to the many errors, uncertainties and imperfections in complainant's bill contained, for a third defense to said bill, severally answering, say:

First. That repeatedly since April 10th, 1910, whenever complainant has sought a new franchise from or contract with the defendant the City and County of Denver, complainant has suggested that it would and has offered to reduce the rates charged and collected by it for water service to the City and County of Denver and its inhabitants, and particularly after the preparation of the proposed contract between the complainant and the City and County of Denver submitted by the Retail Association of the Denver Chamber of Commerce in February, 1914, and before the said contract was voted upon, on, to-wit, February 17th, 1914, and in advocacy of the adoption of such contract by the people of the City and County of Denver,
164 the complainant herein voluntarily suggested and publicly offered that if such contract was adopted it would reduce its rates and charges for water service rendered the City and County of Denver and its inhabitants, except charges for hydrant service and meter rates, to the extent of ten per cent of such charges, provided only that said City and County of Denver, in adopting such contract, would waive the payment of the sum of $50,000.00 per year in said contract stipulated as a charge to be paid by complainant annually for the privilege of being permitted to continue to occupy the streets and public ways of the City and County of Denver, and to collect fees and charges for water service at the same rates which it had heretofore charged; and these defendants say that by reason of the premises complainant is estopped from alleging, claiming or asserting that rates less than those fixed in Schedule "A" of Ordinance No. 44, of the Series of 1890, or less than those fixed in the Leaflet Schedule as rates to be charged for water services, are in any manner unjust, insufficient, unfair, unreasonable or confiscatory.

Wherefore, having fully answered, these defendants pray that complainant take nothing by its bill of complaint herein, but that said complaint be dismissed, and for their costs in this behalf expended.

Fourth Defense.

These defendants, now and at all times hereafter saving to themselves all and all manner of benefit of exception or otherwise
165 that can or may be had or taken to the many errors, uncertainties and imperfections in complainant's bill contained, for a fourth defense to said bill, severally answering, say:

First. That from the year 1908 to and including the year 1913, the gross earnings of complainant gradually increased, the gross earnings for the year 1913 being twenty-eight per cent in excess of the gross earnings for the year 1908; that during the same period the

operating expenses of complainant gradually increased, the total operating expenses for the year 1913 showing an increase of fifty-one per cent over the operating expenses for the year 1908; that during the same period of time the net income or surplus of complainant also gradually increased, the net income or surplus for the year 1913 showing an increase of fifty-eight per cent over the net income or surplus for the year 1908; that during the same period of time the total gallons of water per year delivered by complainant showed a slight yearly increase, the increase in the year 1913, as compared with the year 1908, being a little less than five per cent, and the average daily delivery for the year 1913, showing an increase of approximately five and one-fourth per cent over the average daily delivery in the year 1908.

Second. These defendants say that in the period 1908 to 1913, both years inclusive, the increase in complainants' operating
166 expenses was out of all proportion to its increase in service and to the increase in its yearly gross earnings, but that nevertheless and notwithstanding such excessive increase of operating expenses complainant's yearly net income or surplus increased fifty-eight per cent, and these defendants aver that if complainant will properly, economically and efficiently operate its plant, and avoid useless and needless expenditures and extravagances, thereby reducing its operating expenses, as it may do, the rates and charges fixed by Ordinance No. 25, of the Series of 1914, of the City and County of Denver, will return to complainant a fair, reasonable, just, adequate and sufficient income upon the actual value of complainant's water system and plant.

Wherefore, having fully answered, these defendants pray that complainant take nothing by its bill of complaint herein, but that said complaint be dismissed, and for their costs in this behalf expended.

THE DENVER UNION WATER COMPANY
vs.
THE CITY AND COUNTY OF DENVER et al.

Bill for Injunction and for Other Relief.

This cause being at issue and it appearing to the court that the issues and the conditions as herein presented are so exceptional as to require the appointment of a special master and the reference of this suit to him for the purpose of taking testimony and reporting to this court; all parties hereto consenting;

It is ordered that W. J. Chinn of Colorado Springs be appointed Special Master in this suit with all of the powers conferred upon the Master under the rules of practice for the courts of equity of the United States, and subject to the further orders of this court, with power, subject to review by the court, to pass upon the legal admissibility of evidence. This suit is referred to said Special Master for the purpose of taking all testimony in the suit and reporting to the court said testimony, his findings of fact and such conclusions of law as he may deem essential to the proper advisement of the court. Each party will deposit within ten days $500 to be applied on Master's allowance.

v.
THE CITY AND COUNTY OF DENVER, a Corporation, et al., Defendants.

Amendment to Bill of Complaint.

169 Now comes the complainant above named, by its solicitors, and by leave of court first had and obtained, files herein this amendment to its bill of complaint heretofore filed herein, and hereby amends said bill of complaint by adding thereto and interpolating therein as paragraph Twenty-fourth of said bill the following, to-wit:

Twenty-fourth. By reason of the matters hereinbefore more fully set forth, said Ordinance No. 26, Series of 1914, a copy of which is Exhibit A to this bill of complaint, is now, at all times since its enactment has been, and for the entire period of time during which it is to be or is intended to be effective, will be, unconstitutional, void and in conflict with and prohibited by the provisions of the Constitution of the United States elsewhere in this bill more specifically referred to; and it is, and at all times will, provide for, require and constitute a taking of complainant's property without due process of law, and the denial to complainant of the equal protection of the laws. The rates, practices, requirements and provisions set forth in said ordinance, and each and all thereof, were, are and will be unreasonable, confiscatory, unconstitutional, null and void at all times during which by the terms of said ordinance it is provided, intended or contemplated that the same may remain in effect.

And complainant prays that this amendment may be incorporated in and taken and deemed to be a part of its bill as originally filed herein, and that together they may constitute complainant's bill in this cause; and the defendants be required to answer this amend-
ment as provided by the rules of this Honorable Court, but
170 not under oath or affirmation (answer under oath or affirmation being hereby expressly waived); and plaintiff otherwise prays for relief as it has heretofore in its said original bill prayed.

171 (Endorsed:) Court No. 6274. Div. In Equity. In the U. S. District Court, for the district of Colorado. The Denver Union Water Company, Plaintiff, vs. The City and County of Denver, et al., Defendant. Amendment to Bill of Complaint. Filed May 27, 1915. Charles W. Bishop, Clerk. Hughes & Dorsey, Attorneys for Complainant. No. —.

In the District Court of the United States for the District of Colorado.

No. 6274. In Equity.

THE DENVER UNION WATER COMPANY, a Corporation, Complainant,
vs.
THE CITY AND COUNTY OF DENVER, et al., Defendants.

Answer of the Defendants to the Amendment to the Bill of Complaint.

Come now the defendants in the above-entitled action, by their solicitors, and answering the amendment made by complainant to its original bill of complaint herein, said amendment consisting of the addition of a new paragraph numbered 24, these defendants say:

They deny that by reason of the matters in said bill of complaint and in said amendment set forth, or by reason of any or all of such matters, said Ordinance No. 25, of the Series of 1914, attached as Exhibit "A" to the original bill of complaint, is now or at any time since its enactment has been, and for the entire period, or any period of time, during which it is to be or is intended to be effective, will be unconstitutional, void and in conflict with and prohibited

172 by the provisions of the Constitution of the United States, or in any manner unconstitutional, void and in conflict with any provision of the Constitution of the United States referred to in said bill, or in said amendment, or otherwise, or at all. Deny that said ordinance is and at all times, or at any time, will provide for, require and constitute, or in any manner constitute, a taking of complainant's property without due process of law, and a denial to complainant of the equal protection of the laws. Defendants

deny that the rates, practices, requirements and provisions set forth in said ordinance, and each and all thereof, or each and any of said practices, requirements and provisions, were, are and will be unreasonable, confiscatory, unconstitutional, null and void at all times during which by the terms of said ordinance it is provided, intended, or contemplated that the same may remain in effect, or at any time or at all unreasonable, confiscatory, unconstitutional, null and void, and these defendants allege that said ordinance is now, ever since its passage has been, and until repealed will continue to be a legal and valid ordinance, binding in all respects upon the complainant herein.

173 District Court of District of Colorado. The Denver Union Water Company, a corporation, Complainant versus The City and County of Denver et al., Defendants. Answer of the Defendants to the Amendment to the Bill of Complaint. Filed Jun. 4, 1914, Charles W. Bishop, Clerk. Thomas, Bryant, Nye & Malburn, Attorneys for —— ——, 621-629. Ernest and Cranmer Building, Denver, Colo.

In the District Court of the United States for the District of Colorado.

No. 6274. In Equity.

THE DENVER UNION WATER COMPANY, a Corporation, Complainant,
vs.
THE CITY AND COUNTY OF DENVER, et al., Defendants.

Amendment to the Answer of Defendants.

Come now the defendants in the above-entitled cause, by their solicitors, and tender this their amendment to their answer heretofore filed in said cause, as follows, towit:

In paragraph 15 of said answer, after the words, "in said report," occurring in line 20, on page 19, of said answer insert the following:

These defendants allege and say that at the meeting of the Public Utilities Commission of the City and County of Denver, held on the 4th day of August, 1913, at which meeting the said Commission of Engineers was appointed, the following proceedings, among others, were had and taken:

On motion of Mr. Anderson an advisory committee, consisting of Mr. A. Lincoln Fellows, Mr. C. P. Allen and Mr. E. C. Van Diest,
were appointed to act as an Engineering Committee under the
174 direction of this Commission for the purpose of making careful study of the present value to the City of The Denver

Union Water Company's holdings, and of the proposed projects for furnishing water from the Western Slope for Denver, and the various storage projects on the South Platte River and its tributaries, and of making estimates of the cost of acquiring or constructing a complete water system for the City of Denver by any of the methods proposed, taking into consideration the water supplies available, and to make verbal progress reports from time to time as may be desired, and write a final report at the earliest possible date to this Commission.

And these defendants further allege and say that the powers of said Engineering Commission were as defined in said motion appointing said commission and the members thereof, and not otherwise. The said appointment of a commission is the one referred to in paragraph 15 of complainant's bill of complaint, and the quotations from the report of said commission in the said paragraph of the bill of complaint are a part of the report made by the said Engineering Commission from which the said quotations in the bill of complaint are taken.

Defendants further allege and say that the report of said Engineering Committee, or Commission, referred to and quoted from in paragraph 15 of complainant's bill of complaint, was on the 19th day of January, 1914, received by the Public Utilities Commission and placed on file for future examination; that on the 29th day of January, 1914, at a regular session of the Public Utilities Commission, the following, among other, proceedings were had and taken at such meeting concerning said report, as fully appears upon the minute record of the proceedings of said Commission, to-wit:

'The following was presented by Mr. Van Cise, and on motion was adopted and the Secretary directed to enter in the minutes, upon which Messrs. Van Cise and Anderson voted yea and Mr. Fellows voted no: In directing by our minutes of Monday, January 19th, that the report of the Engineering Committee appointed by this Commission August 3rd, 1913, be received and placed on file for future examination and consideration, the undersigned deem it their duty very briefly to state some of the objections they make to the report and which should be filed with it. The resolution under which the Committee acted did not require or contemplate that it should express an opinion upon the wisdom or desirability of the City's acquiring and constructing a new plant, nor of purchasing the old one. That is a matter which lies wholly with the qualified electors of the City and County of Denver and with this Commission. The estimate by the Committee of the present water plant and system includes much of the plant that is practically worthless to Denver should it become the owner thereof, and in view of
175 the estimates of other engineering committees and experts we deem the value placed upon said plant to be otherwise too high when its age, condition and the manner of its construction are understood. The report does not show such investigation and knowledge as warranted the Committee in fixing the sum it did as the cost of a new plant and system, and the estimate includes items amounting to several million dollars which are not legitimate nor properly to

be associated with a plant constructed solely for supplying Denver with water for irrigation, fire and domestic purposes. For the foregoing and other reasons we cannot approve the report of the Engineering Committee. Signed Edwin Van Cise, Armour C. Anderson.'

Wherefore neither these defendants, nor any of them, are or ought to be in any manner bound by the estimates or conclusions in said report contained.

I. N. STEVENS,
T. M. PATTERSON,
GEORGE L. NYE,
Solicitors for Defendants.

(Endorsed:) No. 6274. Equity. In the United States District Court of District of Colorado. The Denver Union Water Company, a corporation, Complainant, versus The City and County of Denver et al., Defendants. Amendment to the Answer of Defendants. Filed Jun- 4, 1914, Charles W. Bishop, Clerk. I. N. Stevens, T. M. Patterson, George L. Nye, Attorneys for defendants, 621-629 Ernest and Cranmer Building, Denver, Colo.

176 In the District Court of the United States for the District of Colorado.

In Equity. No. 6274.

THE DENVER UNION WATER COMPANY, a Corporation, Complainant,
vs.
THE CITY AND COUNTY OF DENVER et al., Defendants.

Report of Special Master.

177 In the District Court of the United States for the District of Colorado.

In Equity. No. 6274.

THE DENVER UNION WATER COMPANY, a Corporation, Complainant,
vs.
THE CITY AND COUNTY OF DENVER et al., Defendants.

Report of Special Master.

To the Honorable Robert E. Lewis, Judge of the District Court of the United States for the District of Colorado:

1. Pursuant to the Order entered in this suit on May 21st, 1914, and by agreement of the parties, the taking of the testimony herein was commenced on June 3rd, 1914, and thereafter was continued from day to day as is more fully set out in the statement hereto attached, marked "Exhibit A." All of the testimony was taken down

by stenographers appointed by me for that purpose at the request of the parties. All of the testimony, as well as all Exhibits offered on the hearing, are described in "Exhibit A" and are returned and filed with this Report. After the testimony had been produced, the case was fully argued by counsel for the respective parties and
178 printed Briefs have also been filed before me in behalf of each party. Copies of these Briefs are also filed with this Report.

2. In this Report the Complainant, The Denver Union Water Company, is referred to as the "Water Company" and the Defendant, The City and County of Denver, as "the City." Throughout the Report references to the volumes containing the testimony will be found. The capital letter "C" following such reference indicates a volume containing testimony offered by the Water Company and the capital letter "D" in such references indicates a volume of the testimony for the defendants—thus, "Volume 5-C" refers to Volume 5 of the testimony for Complainant.

3. The Water Company has been supplying water to Denver and its inhabitants since October 18th, 1894. The City Council of the City on March 3rd, 1914, passed an Ordinance, known as "Ordinance No. 26, Series of 1914," to regulate and fix the charges by the Water Company for water furnished the City and its inhabitants. This Ordinance by its provisions was to become effective "from and after the date of its passage and approval"—which date was March 3rd, 1914—and was intended to and did reduce the then going (leaflet) rates approximately twenty (20) per cent.

The Bill of Complaint attacks this Ordinance as unconstitutional and void, alleging that the rates fixed by the Ordinance do not permit the Water Company to charge or receive a just or fair return upon the reasonable value of the property necessarily used by it for the delivery of water to the City. The Defendants claim that
179 these rates are fair and reasonable and provide just compensation to the Water Company for the use of its property.

4. In order to decide whether these rates are fair and just, it is necessary to determine from the evidence the following facts:

(*a*) What is the reasonable value of the property used by the Water Company in delivering water to the City and its inhabitants.

(*b*) What return or compensation is the Water Company permitted to earn under the rates fixed by this Ordinance.

5. Many of the facts alleged in the Bill of Complaint are either admitted by the Answer of Defendants or are clearly established by the evidence. These allegations of the Bill are as follows:

(*a*) Paragraphs Fourth (4th) and Sixth (6th) as to the incorporation of the Water Company, the amount of its authorized and issued capital stock, the number and amount of its outstanding bonds, the number and amount of dividends paid to its stockholders and the early history and general description of its water works plant.

(*b*) The allegation of Paragraph Ninth (9th) concerning the incorporation of the South Platte Canal and Reservoir Company, the amount of its issued stocks and bonds, the description of the

property owned by it, the ownership of its capital stock by the Complainant, the lease of its property to Complainant and
180 the relation between said company and the Complainant.

In view of these facts, I find that the property owned by The South Platte Canal and Reservoir Company, insofar as it is used by the Complainant to supply the City with water, must in this suit be considered and appraised as part of the property of the Water Company by it necessarily used to supply the public with water. (Shepard vs. Northern Pac. Ry. Co., 187 Fed. 765, at 809-810.)

(*c*) Paragraph Tenth (10th), concerning the appraisement of all the property owned by the Water Company under the Ordinance of 1907.

(*d*) Paragraph Fifteen (15th) as to the appointment by the Public Utilities Commission of the Public Utility Engineers and the filing of a report by said Engineers, but the allegation that such report was changed before it was filed is not supported by the evidence.

6. The Franchise under which the Water Company operated in the City up to April 10th, 1910, and the schedules of rates in effect up to the time of the enactment of Ordinance No. 26, Series of 1914, are accurately set out in Paragraphs Seventh (7th) and Eighth (8th) of the Complaint.

The Water Company is serving the City and its inhabitants with water, although since April 10th, 1910, it had held no franchise authorizing or requiring it to do so. No water works system capable of supplying water to Denver and its inhabitants, other than that of the Water Company, now exists or has existed since 1894.
181 It appears, however, from Paragraph Twelfth (12th) of the Bill, which is admitted by the Answer, that the City on May 17th, 1910, adopted Section 264-A of the Charter of the City, whereby it created the Public Utilities Commission of the City, directed that an offer of $7,000,000 be made for the property of the Water Company and provided that, in case of the rejection of such offer, steps should be taken to construct and build a water system owned and operated by the City at a cost not to exceed $8,000,000. The Water Company rejected the offer of $7,000,000 for its property. The City has not yet commenced the construction of its own water system.

7. Ordinance No. 26, Series of 1914, was enacted by the City Council as alleged in Paragraph sixteenth (16th) of the Bill. The following additional facts concerning the enactment of this Ordinance are established by uncontradicted evidence:

On July 26th, 1913, the Public Utilities Commission by letter (Exhibit A-46), asked the Water Company on what basis the going (leaflet) schedule of rates had been fixed, and requested a statement of its gross earnings, operating expenses and fixed charges for the preceding three years. The Water Company by letter dated August 16th, 1913 (Exhibit A-47) gave the information requested. This letter also explained the basis of the leaflet schedule of rates and concluded as follows:

"We will be pleased to aid you in investigating these matters and therefore desire to tender to your commission and to the City At-

torney all data in our possession and any information which you may require."

182 The Public Utilities Commission did not seek or obtain any additional information from the Water Company. The Ordinance was drafted at the instance of the Public Utilities Commission and then "regularly initiated by the people under the terms of the Charter" of the City. It was passed by the City Council and approved by the Mayor March 3rd, 1914 (Vol. 5-C, pages 2311-2315). The Water Company had no notice from the Defendants of the proposal to draft or enact the Ordinance, other than that given by its publication in a newspaper on March 2nd, 1914, although as a matter of fact it undoubtedly knew of the entire proceeding. When the Ordinance came before the City Council for consideration the members of that body were of the opinion that it was their legal duty to pass it without making any attempt to determine whether the rates prescribed by it were reasonable. (Vol. 6-C, page 2822.) The Defendants, including the members of the City Council and of the Public Utilities Commission, state in Paragraph Thirteenth (13th) of the Answer that they have not "sufficient knowledge or information upon which to base a belief" as to "the gross earnings, operating expenses, taxes, net income," etc., of the Water Company for any of its fiscal years from 1908 to 1913, inclusive, or as to "the allowances made, or should be made, for depreciation, obsolescence or unusual contingencies."

8. The Water Company insists that the facts above stated authorize and require a modification of the rule of law concerning the presumption as to the validity of this Ordinance which usually prevails in "rate cases." But I do not deem it necessary to

183 consider or decide this question because the evidence clearly requires a finding that the Ordinance is invalid, even when the ordinary rules of law as to its validity are applied to the evidence.

In considering the pleadings and evidence I have been guided by the following rules of law:

(*a*) It is presumed that Ordinance No. 26, Series of 1914, is valid and that the rates fixed by it are reasonable and fair and therefore sufficient to permit the Water Company to earn a fair return for the use of its property by the public.

(*b*) The Water Company has the burden of proving beyond any reasonable doubt that the rates of this Ordinance in fact deny it a fair return on the reasonable value of the property used by it in serving the public.

9. The exhibit filed by the Water Company and identified as "Exhibit C," contains a complete inventory of the property which the Water Company claims constituted the water works plant owned and used by it on November 1st, 1913. This inventory divides the plant into convenient and appropriate classes; and each Class is designated by a letter—thus, Lands and Easements constitute "Class A," Water Rights, "Class B," etc. In this Exhibit each piece of property of a Class is identified by an "Item" number—thus, the Lake

Cheesman lands are "Item 1 of Class A," etc. This classification and method of identification of the property was adopted by the witnesses and parties throughout the hearing of the testimony and is therefore used in this Report.

184 10. The original cost of many of items of property, going to make up the Water Company's plant, cannot be ascertained. The books of its predecessor Companies are not available or do not disclose with accuracy what the original costs were.

The parties agree that neither the par value nor the market value of the outstanding stocks and bonds of the Water Company aid in determining the present value of the Company's property. Therefore, the market value of these stocks and bonds was not proved on the hearing.

11. In this Report the value of the Water Company's plant is found as it existed on May 1, 1914. The evidence shows no material change in the plant between this day and the time when the evidence was heard.

The method of estimating the present fair value of the property, adopted by substantially all the parties on the hearing of this case, and in this Report, is as follows:

Lands and Water Rights are appraised at their present market value.

Estimates of the cost of the reproduction of the structures are made and from such estimated reproduction cost deductions for accrued depreciation are made, so as to determine the estimated reasonable value of the structures in their present condition.

In making such estimates it is assumed that a company attempting to reproduce the structures would not do the work itself, but would cause it to be done under contract, after fair competitive bidding. It is further assumed by the witnesses that the company reproducing the property would incur costs for engineering and

185 superintendence, as well as other costs, in addition to the fair contract cost of the structures.

12. I find from a consideration of all the evidence that the reasonable value of all the property used by the Water Company on May 1st, 1914, as a part of its water plant, for the delivery of water to the City and its inhabitants, is as stated in Table 1, set out in this paragraph.

In this table the figures in Column No. 4 represent the present market value of Class A, Lands; Class B, Water Rights, and Class T, Personal Property. As to Classes C to S inclusive, Column No. 1 represents the estimated fair contract cost of the reproduction, new, of said structures; Column No. 2 represents the estimated cost of the Water Company of the reproduction, new, of said structure, and includes the fair contract cost, plus 12½ per cent. on account of estimated costs for engineering and contingencies; Column No. 3 represents the estimated actual depreciation in value of said structures on May 1st, 1914, and Column No. 4 represents the estimated value of said structures on May 1st, 1914.

TABLE 1.

Class. (Nov. 1st, 1913.)	(1) Fair contract cost, new.	(2) Gross reproduction cost, including 12½% for engineering and contingencies.	(3) Actual accrued depreciation.	(4) Present reasonable value.
A. Lands	.....	.....	.....	$637,814
B. Water Rights	.....	.....	.....	$2,947,617
C. Lake Cheesman Division	$1,000,000	$1,125,000	$26,775	1,089,225
D. Intake—Platte Canon	56,089	63,100	814	62,286
E. Raw Water Conduits	429,925	483,666	5,614	478,052
F. South Platte Canon Division	523,737	589,204	68,040	521,164
G. Raw Water Conduits and Filter	107,790	121,264	47,254	74,010
H. Clear Water Conduits	962,012	1,082,263	182,102	900,161
I. Bear Creek Division	395,361	444,781	48,213	396,568
J. Littleton and Wynetka	34,190	38,464	6,399	32,065
K. Bear Creek Division—Conduits	325,021	365,648	13,360	352,288
L. Cherry Creek Division	108,373	121,920	5,999	115,921
M. Mississippi Avenue Division	135,885	152,871	23,553	129,318
N. West Denver Station	290,628	326,957	125,160	201,797
O. Capitol Hill Division	279,171	314,067	54,125	259,942
P. Ashland Avenue Station	194,138	218,405	98,450	119,955
Q. University Park Station	24,444	27,500	3,451	24,049
R. Montclair Booster Station	3,403	3,828	892	2,936
S. Distribution Pipe System	3,500,000	3,937,500	490,000	3,447,500

T.	Personal Property—Supplies, etc.	190,000	.....	15,314	174,686
	Interest During Construction	805,000	.....	105,455	699,545
	Going Concern Value	.....	.....	.....	800,000
	Value Water Works Plant, Nov. 1st, 1913				$13,475,899
	Deduct Depreciation from Nov. 1st, 1913 to May 1st, 1914, less Additions				60,000
	Reasonable Value of Plant, May 1st, 1914				$13,415,899

187 13. I further find from this evidence that if Ordinance No. 26, Series of 1914, had been in effect during the year ending April 30th, 1915, the gross earning, operating expenses (including taxes and depreciation and the net earning of the Water Company would have been as set out in the following Table No. 2:

TABLE 2.

Gross Earnings under Ordinance No. 26, Series of 1914, and Operating Expenses, Taxes and Annual Depreciation for Year Ending April 30th, 1915.

Gross Earnings year ending April 30th, 1915		$1,093,615
Normal Operating Expenses ending April 30th, 1915	$347,845	
Taxes, ending April 30th, 1915	116,950	
Actual Depreciation, ending April 30th, 1915	140,000	
Total Operating Expenses, Taxes and Depreciation		604,795
Net Earnings or Return		$488,820
Rate of Return on Reasonable Value of Property		.0364+

188 14. The items of property of Class A, (Exhibit C, pages 111 and 119) included in the foregoing Table No. 1, are as follows:

Item. Class A—(Ex. C. pages 111-115).

	Present market value.
1. Lake Cheesman Reservoir and Lands	$160,000
2. Platte River Stone Placer Mining Claim	765
3. Platte Canon Valley	3,065
4. Platte Canon Reservoir Site	9,000
5. Platte Canon Filter Site	1,000
6. Platte Canon Power House Site	1,000
7. Lands Bordering on River	500
8. Lehow Lake	2,500
10. Willard Filter Site	800
14. Dam and Head Gate—Harriman Ditch	1,550
16. Marston Lake Flume	1,137
17. Marston Lake Reservoir	125,000
18. Littleton Mill	4,450
20. Cherry Creek Galleries	4,370
21. Ashland Avenue Reservoir	5,859

22. Ashland Avenue Pumping Station	1,508
24. 10 Lots Cottage Hill Tank Site	1,600
25. West Denver Pumping Station	52,057
26. Tail Race from West Denver Pumping Station	10,731
27. Lake Archer Lands, etc	208,306
28. University Park Tank Site	233
29. South Denver Pumping Station Site	1,083
31. Storage Tank Site Highland Park	533
33. Lands adjoining Cheesman Park	367
34-35-36. Conduits #3, 6, 7	20,000
37. Rights of Way	17,400
Rights of Way through Platte Valley Ranches	3,000
Total Class A	$637,814

189 15. The measure of value of lands adopted in considering the evidence in the present normal market value of similar lands in the same locality. (Minnesota Rate Cases, 230 U. S. 352, at 449-456.) It follows from this rule that the original cost of the lands is not necessarily the controlling factor, though such original cost has been considered along with all the other evidence in determining the value. It likewise follows from this measure of value that when the present normal market value of similar lands in the same locality has been determined, nothing can be added to such value on account of the actual or estimated consequential or severance damages—if any—paid by the Water Company when it originally acquired its lands or on account of the Company's actual or estimated overhead expenses in connection with the purchase of these lands. These expenses represent original costs of the lands and not their present market value. In considering the evidence concerning the value of these lands I have assumed that we may take into consideration their adaptability or availability for any useful purpose, provided the evidence shows that lands possessing such adaptability or availability have any special market value on account thereof: but the final question in my judgment, always is—what is the present market value of similar lands in the same locality and not what are these lands worth now to the Water Company for the purposes for which they are now used.

16. In considering the testimony concerning the market value of lands, greater weight has been given to the testimony of the witnesses Wall, Bowles, Newcomb, Conaway and Watson who testified on behalf of the Water Company, than to the testimony
190 of Messrs. Armour C. Anderson and Carper, who testified for the Defendants, because it clearly appears that the Complainant's witnesses made a more careful examination of the property to be appraised and were better informed as to present market value of similar lands in the vicinity. The above named witnesses were all residents of Colorado and had special knowledge as to land values in the vicinity of the lands involved in this case.

The Company contends that certain of its lands have a higher market value than other lands in their immediate vicinity because

they are peculiarly available as reservoir sites or specially adapted to water works uses.

Messrs. Metcalf and George G. Anderson, two of the Company's witnesses, have attempted to appraise the lands claimed to possess this peculiar value. The values assigned to such lands by Messrs. Metcalf and Anderson are in general the same as the values at which such lands were appraised by the witnesses Freeman, Holman and Hazen, who were members of the Joint Board of Appraisers of 1907.

These witnesses, Messrs. Metcalf, Anderson, Freeman, Holman and Hazen, are men of high standing in their profession and have had a very broad experience in the business of constructing and operating and appraising water works plants. None of them, however, possessed any expert or other special knowledge concerning the present market value of lands in Colorado. In fact, none of them claimed to be an expert on this question. Their estimate of the value of such lands to the Water Company owning and using them as a part of its system is no doubt entitled to very great weight, but their opinion as to the present normal market value of sim-

191 ilar lands in the vicinity is, in my judgment, entitled to little weight because of their lack of knowledge of such present normal values.

17. Metcalf and Anderson have appraised the following lands at sums in excess of the values assigned to them by the expert real estate appraisers who testified for the Water Company:

Item 2. The Platte River Stone Placer Mining Claim.

Item 3. Platte Canon Valley.

Item 5. Platte Canon Filter Site.

Item 6. Platte Canon Power House Site.

Item 20. Cherry Creek Galleries.

Wall and Bowles, witnesses for the Water Company, based their appraisement of these tracts on the present market value of similar lands in the same locality. Metcalf and Anderson believed these lands peculiarly adapted to water works purposes and appraised them at a higher value. I have adopted the Wall and Bowles appraisement of these lands, except as to Items 5 and 6, because the evidence does not lead me to believe that any of the tracts have such peculiar and obvious adaptibility for water works purposes, over and above other lands in the same locality, as to give them any market value above that of the neighboring lands. Items 5 and 6 I find are reasonably worth slightly more than the sums assigned by Wall and Bowles.

18. The Lake Cheesman Reservoir Lands (Item I, Class A) are appraised by Metcalf and Anderson at $200,000, and by Van Diest, witness for Defendants and a member of the Board of the Public Utility Engineers, at $40,799.

192 The record contains very little evidence as to the market value of similar lands. The lands are peculiarly adapted to reservoir uses and are more valuable for such uses than any other lands on the river. For reasons already stated, the testimony of the witnesses Metcalf, George G. Anderson, Freeman, Holman, Hazen

and Van Diest, concerning the market value of these lands cannot be given great weight. These witnesses believed that a company desiring to acquire such a large body of land usually finds it necessary to pay for it several times its normal value and this belief influenced their judgment in their appraisements. The Lake Cheesman lands cost the Water Company not less than $160,000 (Miller, Vol. 2-6, pages 444-445; Vol. 3-6, pages 1399-1400; Vol. 4-6, pages 1492 and 1535-1536). Taking into consideration all the evidence, I believe it reasonable to appraise these lands at $160,000.

19. The Marston Lake Reservoir lands (Item 17, Class A) are appraised by Metcalf and Anderson at $168,000, and by the Engineers of the Public Utilities Commission through the witness Van Diest, at $124,160. Wall and Bowles, considering them merely as dry lands without water, appraised them at $71,780. They were purchased by the Water Company many years ago when the market value of land was much less than it is now. The purchase price was about $87,000. In view of all the testimony, I have appraised them at $125,000.

193 20. The Rights of Way (Items 34, 35 and 36, Class A) owned in fee by the Water Company, cost about $19,166 and are appraised by Wall and Bowles at $23,528. These witnesses, however, included in their estimates some amount on account of the damages they assumed the Water Company had to pay the original owners in the nature of severance or consequential damages. (Vol. 4-6, 1560-1562). I find from the evidence that the reasonable value of the property is $20,000.

21. I find from the evidence that the following tracts of land, inventoried in Class A, do not constitute any useful part of the plant with which the Water Company is serving the public and therefore I have excluded them and all their appurtenant structures from the property to be further considered or appraised in this Report:

Item 9. Phebe Strong Ranch.
Item 10. Wm. Strong Ranch (Except Willard Filter Site).
Item 11. Becky Archer Ranch.
Item 12. Frank Archer Ranch.
Item 13. Mountain Reservoir Site.
Item. 15. Harriman Lake.
Item 19. Sullivan Reservoir Site.
Item 20-A. Woodbury Land.
Item 23. DeLappe Place.
Item 24. Cottage Hill Tank Site, consisting of 43 lots; thirty-three (33) of these lots are excluded and ten (10) included as a part of the operating plant.
Item 30. Office and Superintendent's Residence, Littleton.
Item 32. Lots in Cottage Hill.

194 22. The Water Rights inventoried in Exhibit C (Class B, pages 117 and 118) fall into two groups—appropriations purchased by the Water Company after they were initiated and perfected by others and appropriations originally initiated and perfected by the Water Company or its predecessors.

The purchased Water Rights are:

Items 1, 2, and 3, Platte Canon Ditch.
Items 13, 16 and 17, Harriman Ditch Company.
Item 11, Northern Colorado Irrigation Company.
Item 14, Soda Lakes Reservoir Company.
Item 21, Rough and Ready Mill Ditch.
Item 22, Platte and Denver Ditch.

23. The City Attorney contends (page 173 of printed brief) that the Water Company owns no title or interest in any of these Water Rights but that all of them are owned by the City.

When the Company acquired its purchased Water Rights they were all "adjudicated rights." At the time of such purchase, each grantor of the Company was vested with a right to divert and use a certain quantity of the water. This right was, under the Colorado rule, a property right in the highest sense, and capable of transfer, separate from the lands to which it was appurtenant. (Strickler v. Colorado Springs, 16 Colo. 61, at 68, et seq., Ironston Ditch Co. v. Ashenfelter, et al., 57 Colo. 31, at 39-40.) The property right so purchased by the Water Company has not been transferred by it to the City for its inhabitants. The appropriations have been and now are used to supply the City with water. Such use was not an abandonment of the rights and certainly did not operate as a
195 sale or transfer of them. No decision of any Court has been cited which holds that the act of supplying water to a city by a private company operates to transfer to the city the water rights which constitute the source of supply. These Water Rights were purchased and paid for by the Water Company. They have been used by it to discharge its legal duty of supplying water to the city. They have not been sold or conveyed to the City. They are the property of the Water Company.

24. The facts concerning the Water Rights claimed by the Water Company by original appropriation, are as follows: The Water Company (or its predecessor) at times when franchise contracts with the City obligated it to supply water to the inhabitants of the City, diverted from the natural streams of Colorado unappropriated water which it used as a part of its supply to its consumers in the City. Its franchise contracts with the City have been limited to fixed short periods. The contracts between the Water Company and its private consumers have been simply permits or licenses covering usually six months only. The rates have been paid in advance by the consumer and a failure on his part to pay or a violation of any of the reasonable rules of the Company has operated to terminate his right to use the water. (Exhibits A-34, A-35 and A-36.) The consumer has, under these permits, been merely a licensee who for a sum paid in advance was allowed to use water on named premises, for specified purposes.

The parties hereto agree that such a diversion and beneficial use of the unappropriated water of a natural stream is sufficient to initiate and perfect a right to continue to use beneficially the volume
196 of water so appropriated. The City claims that the ownership of the appropriations so initiated is not in the Water Company, but is in it or its inhabitants—because these inhabitants by actually applying the water to a beneficial use have, as it claims, "per-

fected" and become the "original appropriators" of such water rights.

Where the unappropriated water of a natural stream is diverted and carried to the place of use by one and applied to a beneficial use by another, the "appropriation" is in Colorado "perfected." The ownership of the "appropriation," under such circumstances, is or may be fixed by contract between the one who diverts and the one who beneficially applies such water. It is plain that such parties by contract between themselves may vest the ownership of the appropriation in whom they please. This I understand to be the rule adopted by the Supreme Court of Colorado in City of Denver v. Brown, 56 Colo. 216.

The application of this rule to the facts of this case, places the ownership of these Water Rights in the Water Company. There is no testimony, in the voluminous record accompanying this Report, from which it can be fairly inferred that any consumer of the Water Company at the time he paid his water rates and received his license, believed or claimed he was making an appropriation of the water of a natural stream of Colorado or was acquiring as against the Water Company any right of any nature to the use of water except as stated in that license.

I find that these Water Rights are owned by the Water Company.

197 25. The measure of value of water rights used by me is the present market value of similar water rights in the same locality. No addition to such market value is made because appropriations yielding the large volume needed to supply the City are assembled under one ownership or because the use of this water for domestic and city purposes may be, as stated by some of the witnesses, a "higher" or a "preferred" use as compared with the use of water for irrigation or manufacturing.

26. The testimony concerning the market value of water rights relates almost wholly to rights used for irrigation. Several of the witnesses made estimates of the present market value of the company's water rights for irrigation uses—that is, these witnesses assumed that the water was to be used, not to supply the City, but to irrigate the lands in its vicinity and upon this assumption attempted to measure the value of these water rights by the market value of other water rights now being used to irrigate similar lands. Some—if not all—of these witnesses further assumed that such a change in the place and character of use would necessarily result in considerable loss of water in transit through seepage and evaporation. Such assumed loss was taken into consideration by the witnesses with the result that their estimate of the market value of these water rights for irrigation was reduced to the extent of such loss. These water rights under existing conditions are peculiarly well located for a source of City supply and deliver water with great efficiency and small loss in transit. Therefore the appropriation used for irrigation, which may fairly be compared with these Water Rights, are such irrigation rights as have a like efficiency for the irrigation of the lands to which they are applied.

198 27. Applying the foregoing measure of value, I find the present market value of the Company's Water Rights (Class B, Ex. C, pages 117-118) as follows:

Group 1, being Items 1, 2, 3, 4, 13, 14, 15, 16, 17 and 21.	$949,500.
Item 5, Denver City Water Co. and	
" 6, Mississippi Street (with 21 & 22)	200,000.
" 7, Cherry Creek Galleries	66,000.
" 8, Platte Canon Filter Galleries	65,000.
" 9, " " 34" Conduit	24,750.
" 10, " " 40" "	30,000.
" 11, Northern Colo. Irr. Co.	1,250.
" 12, Lake Cheesman	1,611,117.
Total Class B	$2,947,617.

28. The sum at which Lake Cheesman Water Rights (Item 12, Class B) are appraised in this Report, results from a consideration of the following facts.

The market value of an acre foot of water from the Antero Reservoir has been from $25 to $35. This reservoir is located many miles above Lake Cheesman on the south fork of the South Platte River; its structures are inferior to and less valuable than those at Cheesman and its appropriations are later in date and therefore less valuable. Its water is used to irrigate land near Denver.

Many rights in the Standley Lake have been sold at the rate of $50 per acre foot, payable in bonds selling for 85 to 90 per cent. of their face value. The Standley Lake appropriations are junior to those of Lake Cheesman and its structures are less valuable. Its water is used to irrigate land near Denver.

199 Rights in other reservoirs which supply water to irrigate lands at greater distances from Denver—in Northern Colorado—have been selling at prices equivalent to $50 to $70 per acre foot. This water is chiefly used late in the irrigation season when the demand is great and market value high.

Lake Cheesman delivers water to the City with small loss in transit, is efficient as a source of domestic supply and is available for use and used in periods when the supply of water in the natural streams is limited and the demand for water is great.

These facts, in my judgment, make it reasonable to consider rights in Lake Cheesman more valuable than rights in the Antero or the Standley Reservoirs.

All these facts in my judgment make it clear that the Cheesman appropriations as now used, ought to be valued at a higher sum than the going market price of the Antero or the Standley Lake waters. I have adopted a unit price of $55 per acre foot for these Rights. There is much evidence in this record which tends to establish a higher value. I have refused to adopt the unit price of $60 per acre foot—the appraisement made by many witnesses—because I do not believe the evidence warrants the conclusion that water rights used in the immediate vicinity of Denver have ever sold for

as high a market price as the best rights in Northern Colorado command.

29. There are many estimates in the record of the volume of water available for storage in Lake Cheesman under its decreed appropriations, limited by capacity of the reservoir. I am of
200 the opinion that the testimony and estimates of the witnesses George G. Anderson and George Bull should be given great weight and largely guide in the conclusion finally adopted. Mr. Anderson's estimate of the average available storage of Lake Cheesman, based on fourteen years of records of stream flow and other available data, is about 55,339 acre feet. That of Mr. Bull for a like period is about 51,700 acre feet. Weighing these two estimates in connection with all the other evidence on the same subject, I find 54,000 acre feet to be a reasonable estimate of the water storable in and available for delivery annually by the Cheesman Reservoir.

This volume of water at the unit price of $55 per acre foot, is of the gross value of $2,970,000. The land and structures of this property are appraised as follows:

Lake Cheesman Lands	$160,000.
" " Structures	1,098,225.
Total Lake Cheesman Lands and Structures	$1,258,225.
8% interest thereon	100,658.
Total deduction from gross value	$1,358,883.

The resulting net value of the Lake Cheesman Water Rights is $1,611,117, which I find to be their present value.

30. Group I, of Class B of Water Rights, I find from the evidence to be of the net value of $949,439, estimated as follows:

201 The estimated volume yielded by these Water Rights is 37,000 acre feet of the value of $55 per acre foot, making a gross value of ..... $2,035,000.

Value of Lands and Structures appurtenant	$1,005,149	
Interest 8%	80,411	
Total deduction		1,085,560.
Net Value of Rights		$949,439.

31. The lands appurtenant to the Cherry Creek Galleries (Item 7, Class B) and to the Platte Canon Filter Galleries (Item 8, Class B) are appraised by me at a smaller sum than by Metcalf and Anderson as set out in Exhibit C. Therefore, the deductions from the gross value of these Water Rights are less and the net value found by me greater.

The Water Rights described as Items 7, 8, 9, and 10 are peculiarly available and efficient as a source of City supply. For irrigation

uses they would be less efficient. The testimony related to their present market value for irrigation uses. The evidence convinces me that as a source of City supply they are reasonably worth the sum at which they are here appraised.

32. In the deductions made above from the gross value of Water Rights, one year's interest at the rate of eight (8) per centum on the land and structure value is included. This interest rate was adopted by the Water Company in its estimates and not objected to by the Defendants.

33. I have given great weight to the testimony of Messrs. Hazen, Freeman and Holman concerning the estimated cost of the
202 reproduction of the structures of the plant (Classes C to S inclusive) and accrued depreciation, and the reasonable allowance for future depreciation. These witnesses were members of the Joint Board of Appraisers of 1907. As members of this Board, they considered the property, not as expert witnesses, but as disinterested appraisers acting under oath in a quasi judicial capacity. They are engineers of large experience in designing, constructing, operating and appraising water works plants.

34. The estimates of the fair contract cost of the reproduction of the Lake Cheesman structures (Class C, Exhibit C, pages 119-133), when placed on an approximately correct comparable basis (See Exhibit "A-98," table "A" and Exhibit "A-99," table "C"), are as follows:

Metcalf and Anderson	$1,020,778.
Gaffy	947,600.
Bickel	891,430.

The difference in these estimates is largely accounted for by two Items. One Item—subdivision A of Item 6, amounting to $84,748—is wholly excluded by Bickel and in part by Gaffy. This was an error as the witnesses themselves practically admit. Insofar as this Item was excluded by them, their estimates are too low.

The other Item—subdivision C of Item 6—concerns the estimated cost of the reproduction of the masonry of the dam. The estimate of Metcalf and Anderson for this work is $485,320; that of Gaffy is $421,480 and that of Bickel, $389,050. Mr. Bickel's estimate of the quantity of stone necessary for this structure was too small as the evidence demonstrates. His estimate is further based
203 upon an erroneous assumption as to the character of the stone work of the upper face of the dam.

The contract price paid for this masonry work was $443,474. This contract price did not include the cost of that portion of the first dam incorporated in the existing dam. The evidence shows that the cost of the reproduction of this work today would be greater than was the cost of its original construction.

Giving consideration to all the estimates, as well as to the original cost of the structures, the sum of $1,000,000 is adopted as a reasonable estimate of the present fair contract cost of the reproduction new of the whole of Class C.

35. The estimates of the witnesses as to the cost of the reproduction (new) of Classes D to H, inclusive (Exhibit C, pages 135-215) do not differ greatly. Such differences as exist are due in part to different assumptions concerning the proper method of constructing the slow sand filters and concerning the amount of excavation and back filling for conduit trenches. I am satisfied from a consideration of all the evidence that the estimates of Metcalf and Anderson are the more reasonable and they are adopted by me for all these Classes, with the proper correction in Class F for the errors pointed out by Mr. Metcalf (Vol. 8-C, pages 3695-3696).

36. From the property inventoried under Class I (Ex. C, pages 243-269), Bear Creek Division, I exclude the Harriman Lake structures (Item 6, page 245, Ex. C). The estimate of Metcalf and Anderson of the cost of reproduction new of the remainder
204 of this Class is sustained by the evidence. Its amount is $395,361.

37. From the property inventoried in Exhibit "C" under Class J, (Exhibit C, pages 271-284), there are excluded the following items connected with the offices and superintendent's residence at Littleton:

Item 2-B, Fences, etc.	$475.00
Item 3, Walks	436.00
Item 6-A, sub-items 1, 2 and 3, frame dwelling, barn, etc.	7,594.00

Item 5, the machinery at Littleton Mill, is appraised by Metcalf and Anderson at $30,353. The testimony of the witness O'Ryan (Defendants' Exhibit 69) tends to prove that this machinery can be reproduced for a much smaller sum. I appraise this item at $20,000. After these exclusions and deductions, I appraise this Class at $34,190.

38. I have excluded the structures at Sullivan Reservoir (Item 5, page 302, Exhibit C) from Class L and find the reasonable estimated cost of reproducing the remainder of this Class to be $108,373. The Metcalf and Anderson estimates of Classes K and of M to R, inclusive, are well sustained by the evidence.

39. The witnesses estimate the reproduction cost of the Distribution Pipe System, Class S (Exhibit C, pages 365-390), as follows:

Metcalf and Anderson	$4,333,412
Public Utility Engineers	3,954,076
Gaffy	3,749,365
Bickel	3,671,185
Gordon	3,331,552
Hill	3,403,909

205 Two Items, "Taps for Private Consumers" and "Parallel Track Constructions," aggregating about $250,030, are found only in the Metcalf and Anderson estimate. The sum of $105,000 should be deducted from the Gaffy estimate to bring it to a fair comparable basis with the others—this sum represents the difference growing out of a different assumption as to wage scale.

The estimates of Gordon and of Hill are in my judgment entitled

to less weight than those of the other witnesses, because of the limited experience of these witnesses concerning construction work involved in the estimates, and also because these witnesses made less careful study and investigation of this distribution system.

The item of Pavements (Item 17, Class S, Exhibit C, pages 369-370), amounting to $539,558, is similar to the Pavement item mentioned in the case of Des Moines Gas Co. v. City of Des Moines (decided by the Supreme Court of the United States June 14, 1915) and is excluded on the authority of that decision.

Items 19-C, 20-A, B and C and 21-A (Ex. C, pages 386, 387 and 389) amounting to $109,992, are the estimates of those added costs of reproduction occasioned by the subsequent construction of tracks of railways and conduits of telephone companies over or parallel to or very near the mains of the water system. The presence of these tracks and conduits in the streets adds nothing to the life or utility of these pipes. Such tracks and conduits were not paid for by the Water Company. A change of a few feet in the location of the mains would avoid these obstructions. The exclusion of these Items
205½ is in my judgment the reasonable method of reproduction of the pipe system and is in accordance with the opinion in Des Moines Gas Co. v. City of Des Moines.

Item 25—Taps for Private Consumers (page 390, Ex. C), estimated by Metcalf at $140,038, concerns the estimated cost of the reproduction of the service taps now incorporated in the Water Company's mains and to which the service pipes of the consumers are attached. Under the rules of the Company the taps and the cost of their installation have been paid for by the consumers. Because these taps are incorporated in the mains, the Company claims they are its property. But they are likewise attached to the service pipes belonging to the consumers and paid for by them. To my mind it is inequitable to require the consumers to pay the Company a return on the value of taps paid for in full by them. The Company's claim as to this Item is disallowed.

I find from the evidence that a reasonable estimate of the reproduction cost of the Distribution Pipe System (less the above exclusions) is $3,500,000. This is in excess of the estimates of the Public Utility Engineers and of Bickel and of Gaffy. The last-named estimates are unduly low. The cast iron pipes and the specials constitute a large part of this Class. The unit prices adopted for such pipes and specials therefore, materially affect the amount of the estimates. The market price of these articles fluctuates rapidly. This market price was unusually low when the witnesses last named made their estimates, for which they used the going low price as their unit price. Metcalf and Anderson adopted as their unit price the average market price for ten years. When the Joint Appraisement of 1907 was made, the then going price of these pipes
206 and specials was unusually high; the Board, however, rejected the going prices and adopted the average price of a series of years. I believe that the fairer method of making such an estimate is to make use of unit prices based on the average of a series of years. This is particularly true in a case such as the present

one, where such average price is much nearer the actual prices paid by the Company for its pipes. Hence the Metcalf and Anderson estimate in this regard seems the fairer. The estimates of Bickel, Gaffy and Van Diest (Public Utility Engineers) seem too low in regard to fair cost of the excavation and back filling of the trenches necessary for the excavation of the distribution system.

40. The Personal Property (Ex. C, pages 391-395), constituting Class T, is appraised by Metcalf and Anderson at $247,883, and by the Public Utility Engineers (Van Diest) at about $214,480. Items 19 and 20 (pages 393, Ex. C) consist of personal property on the Platte Valley Ranches used for farming purposes.

The Metcalf and Anderson valuation includes the present market value of the personal property plus certain sums added on account of overhead charges, superintendence and interest on the investment.

This property is such a stock of supplies as the owner must have on hand to properly operate the water works plant. The owner is entitled to a fair return on such property while held in stock ready for use, even though it has not been actually incorporated in the operating plant. Therefore, to add anything in the nature of an interest or carrying charge to the going market value of such property is unfair and clearly erroneous. Nor does it seem reasonable to enhance the present market value of this per-
207 sonal property by any allowance for estimated overhead charges of the Water Company. It is more than probable that all overhead expenses in connection with the purchase, distribution and storage of this personal property are carried into the Company's operating expenses proved and allowed in this Report. I have no doubt that the operating expenses of the Company for the years 1913 and 1914, proved on this hearing, include all overhead costs, superintendence, etc., relating to this personal property. To allow such costs as operating expenses and at the same time to include them in the valuation of the personal property on which the Company is entitled to a fair return, would be erroneous. Deducting Items 19 and 20, above referred to, and rejecting all addition on account of interest, overhead charges, etc., I appraise Class T at $190,000.

41. A reasonable estimate of the reproduction cost of such a plant as the Water Company's must include some allowance for "interest during construction." This involves an estimate of a fair sum for interest on the money necessarily expended in the construction of the plant from the time the work is commenced until the plant begins to earn an income. The Board of Appraisers of 1907 estimated this interest at $850,000 on the assumption that the lands and structures of the plant cost new about $10,604,000. These lands and structures are appraised by me at a somewhat less value and I find an estimate of $805,000 for interest during construction is reasonable and fair. This Item is a part of the cost of the construction of the water works plant and suffers depreciation in the same degree as the other parts of the plant.

208 42. The Water Company (Ex. C. page 64) claims that $120,000, on account of "preliminary Expenses and Organization," should be included in the estimate of the value of the property it is using to serve the public. Mr. Metcalf explained this Item as follows (Vol. 4 (C) page 1700):

"That Item is assumed to cover the expenses of preliminary investigation by engineers and others, the incidental legal work, the formation work, if you like; the work of acquiring the franchise—that is, the legal work—filings, attendance on meetings incident to that, and, in short the general preliminary expenses which might be incurred incidental to an investigation of the project and the organization of the corporation."

The witness further states that in his judgment, the amount was reasonable, conservative.

The allowance elsewhere made for the Company's Engineering and Contingencies is, in my judgment, reasonably sufficient to cover all preliminary investigation by Engineers and others. No franchise exists in this case and the cost of its acquisition cannot be allowed. This Item is disallowed.

43. In the printed argument of the Water Company (pages 627-628) the claim is made that $100,000 should be included in the rating base as the necessary amount of working capital the Company needs to carry on its business. The testimony of Metcalf, relied on in support of this claim (Vol. 4 (C), page 1750) does not authorize its allowance. The Company requires its consumers to pay in advance at the beginning of each six months period and hence usually has in its possession a sum of money greatly in excess of $100,000—paid by consumers before it has actually been
209 earned. This is a sufficient working capital. It would be unreasonable to require the consumer to pay a return on such working capital.

44. The allowance for the Water Company's Overhead charges in the nature of Engineering and Contingencies of 12½% of the estimated fair cost of reproducing the structures (Classes C to S, inclusive) is, in my judgment, fair and well sustained by the evidence.

45. The foregoing estimates of the value of Classes C to T inclusive, refer to the reproduction new of such property. But in fact it is not new. It has been in use for varying periods and has depreciated. Such accrued depreciation must be considered in determining its present value. The extent of such depreciation can be ascertained only by an examination of the property to enable one to see and determine its present condition. Such an examination was made by the witnesses Metcalf, Van Diest, Freeman, Holman and Hazen. The testimony of these witnesses authorizes and sustains as fair and reasonable the allowances for accrued depreciation set out at pages 62, 63 and 64 of Exhibit C. Similar allowances have been adopted by me and are found in Column No. 3 of Table No. 1, in Paragraph 12 hereof.

46. The Water Company claims that after its physical property has been valued in the manner above described, there inheres in the plant an additional element of value designated as "Going Con-

cern Value." The Defendants, admitting that such an element of value exists in a "purchase case," have contended that it
210 cannot be considered in a "rate case." Such was the contention of the parties up to June 14th, 1915, when the Supreme Court of the United States rendered its opinion in Des Moines Gas Company v. City of Des Moines, et al.

This opinion declares that going concern value "is a property right, and should be considered in determining the value of the property, upon which the owner has a right to make a fair return when the same is privately owned although dedicated to public use." Defendants now contend that such "property right" has been sufficiently considered when the physical property of the plant has been appraised at a sum in excess of its "junk" or "wreckage" value.

My understanding of the opinion in the Des Moines Gas case is as follows:

(*a*) "Going Concern Value" is "the value which inheres in a plant where its business is established, as distinguished from one which has yet to establish its business."

(*b*) That "there is an element of value in an assembled and established plant, doing business and earning money, over one not thus advanced, is self-evident. This element of value is a property right, and should be considered in determining the value of the property, upon which the owner has a right to make a fair return when the same is privately owned although dedicated to public use."

(*c*) In considering and estimating this element of value, "each case must be controlled by its own circumstances."

Has this element of value been considered and appraised in the valuation found for the physical property (including Water Rights) of the Company, in the preceding pages of this Report? Such valuation of the physical property represents and is intended to represent the present market value of the Company's Lands (Class A), Water Rights (Class B) and Personal Property (Class T), with
211 no addition whatsoever because such property constitutes part of a long established plant doing a business which yields an income. The valuation of the other Classes of the property is intended to represent its present value determined by its estimated reproduction cost (new), less its actual accrued depreciation, with nothing added because the property is a part of "an assembled and established plant, doing business and earning money." Such valuation of the entire property has been made precisely as if the plant were about to commence serving the public, with its business yet to be established.

The plant is one "where its business is established" and is "an assembled and established plant doing business and earning money." It follows that the "element of value,"—the "property right"—going concern value, remains to be appraised.

The value at which it is appraised by the witnesses is: Freeman, $1,100,000; Holman, not less than $1,154,788; Hazen, not less than $1,100,000; Metcalf, $1,200,000; Van Diest (estimated as development expense) at about $375,628. These estimates are entitled to great consideration and authorize an appraisement of this element

at not less than $1,100,000. Nevertheless, after considering the entire history of the Company and its relations to the City and having due regard to the fact that the City is located in a semi-arid region where the Company has a monopoly of supplying a necessity, I cannot believe it reasonable to appraise Going Concern Value at any sum in excess of $800,000. My opinion is that the Company's witnesses assumed that too long a period and too great an expenditure of effort and money would be necessary to establish such a "going concern" in such a city as Denver. There is no absolute
212 standard by which the fair value of this element can be determined and I adopt $800,000, because no matter how often I have considered the evidence and the arguments, my mind always comes back to this amount as reasonable and fair to all the parties.

47. The property described in "Exhibit C," refers to the plant as of Nov. 1st, 1913. To bring the valuation down to May 1st, 1914, it is necessary to make proper deduction for depreciation between Nov. 1st, 1913 and May 1st, 1914 and to consider the value of any additions to the property during this period. A consideration of such depreciation and additions renders it necessary to deduct $60,000 from the value of the plant as it was on Nov. 1st, 1913 and such deduction is made in the Table No. 1 of Paragraph 12 hereof.

48. The witnesses who testified concerning the reasonable value of the entire plant, appraised it as follows:

Freeman	$15,370,000
Hazen	15,300,000
Metcalf and Anderson	16,000,000
Holman	16,614,719

I have excluded from consideration a portion of the property included in the estimates of these witnesses and have valued many elements of the plant at lower sums. A new plant capable of serving the public with like efficiency cannot, according to the evidence, be built for $13,415,899. Giving due consideration to all the evidence, I find that $13,415,899, is the fair and reasonable
213 value of the property used by the Water Company for the convenience of the public.

49. I find that the Water Company's gross return for the year beginning May 1st, 1914 and ending April 30th, 1915, under the rates prescribed by Ordinance No. 26, Series of 1914, would have been $1,093,615.45. This estimate excludes the item of $12,269.44 for "rentals, Ranch Income," etc., set out in Exhibit A-107. It includes $25,173.72 on account of the delinquent water licenses set out in Exhibit A-107.

Ordinance No. 26, Series of 1914, permits a slight increase in the rates charged certain large consumers using meters. The Company claims the going meter rates have prevailed so long and commercial conditions affecting them are such that they cannot be increased. If the increase can be made the added revenue will be about $16,560,40. I have included this sum of $16,560.40 in my estimate of

the possible earnings of the Water Company under the new rates. About 2.06 per cent. of the gross revenue of the Company is earned for water furnished to consumers outside the City. These consumers pay the old (leaflet) rates and the above finding concerning the Company's gross revenue under the new rates is upon the assumption that these outside consumers will continue to pay the old rates.

50. I find that the reasonable and necessary allowances for normal operating expenses, taxes and depreciation of the plant of the Water Company for the same year (beginning May 1st, 1914 and ending April 30th, 1915) are as follows:

214	Operating Expenses	$347,845
	Taxes	116,950
	Annual Depreciation	140,000
	Total Operating Expenses, Taxes and Depreciation	$604,795

The basis of the foregoing findings as to Operating Expenses and taxes is Exhibit A-107. Deductions of the Ranch Expenses are made in the above estimate and proper deductions from taxes are made on account of taxes on the property heretofore excluded.

The allowance of $140,000 for annual depreciation is based largely on the testimony of Mr. Hazen, who estimated such depreciation at $150,000. His estimate was based on a higher appraisement of the plant than mine.

51. It results from the facts found in Paragraphs 49 and 50 hereof that the net earnings of the Water Company for the year ending April 30th, 1915, under Ordinance No. 26, Series of 1914, would be $488,820. The reasonable value of the property used by the Water Company in serving the public I have found to be $13,415,899. The rate of return allowed under this Ordinance is .0364+ of the reasonable value of the plant.

52. The evidence shows clearly that the Company's plant as a whole, is as stated by Mr. Metcalf (Vol. 4-C, page 1648):

"In excellent condition. The quantity of water is abundantly in excess of the needs of the community, the pressure under which the water is furnished is good, comparing very favorably with the records in the majority of our American cities. In general, I believe that the service furnished by the Denver Union Water Company compares favorably with that furnished by any other water works system in the country."

A number of citizens of Denver testified that the volume of water or the pressure in their several homes was unsatisfactory. In
215 practically every case mentioned by these witnesses the evidence shows that the deficient delivery of water was caused by the service pipe or the plumbing of the property owner and not by defects in the plant of the Company.

The testimony of the witness Goldsmith concerning the volume of water and the efficiency of the system is entitled to great weight and fully justifies the above finding. Mr. Goldsmith was for many years employed by the National Board of Fire Underwriters to make

tests of the water supply systems in American cities for the purpose of determining the ability of such systems to furnish water for fire protection. He has made about forty such investigations in the larger cities of the United States. His investigation in Denver consumbed about three months. It was made before the present suit was commenced. His work involved a thorough test of substantially every portion of the system. It was an independent investigation, made by one fully qualified and for the benefit of persons having no financial interest of any nature in the Water Company. The report made by Mr. Goldsmith and his testimony in this case show that he found the system adequate and reliable and in efficiency equalled only by one other of the plants he had investigated.

53. The Water Company is entitled to a fair return upon the reasonable value of the property used by it for the convenience of the public unless, considering the nature of the service rendered by it, such a return is not fair and just to the public.

216 The rule in this regard is stated in the case of Willcox v. Consolidated Gas. Co., 212 U. S. 19 at 48 as follows:

"There is no particular rate of compensation which must, in all cases and in all parts of the country, be regarded as sufficient for capital invested in business enterprises. Such compensation must depend greatly upon circumstances and locality; among other things, the amount of risk in the business is a most important factor, as well as where the business is conducted, and the rate expected and usually realized there upon investments of a somewhat similar nature with regard to the risk attending them."

The evidence shows that the going rate of interest for loans on business and residence properties in Denver is about six (6) per cent. and on ranch property near Denver about seven (7) per cent. The interest rate provided by the Colorado statute is eight (8) per cent. The current bank rate on good risks is about six and one-half (6½) per cent. According to Exhibit A-59, the average rate of interest paid by the Company for money received for sale of its bonds between 1901 and 1913, was over six per cent., although nominally five per cent.

I find that 3.64 per cent. is not a fair or just return for the use of the property of the Water Company by the public.

The evidence shows the service of the Water Company is of such value as to render fair to the public, rates which are sufficient to yield a fair return on the reasonable value of the property devoted to the use of the public.

I find that the rates prescribed by Ordinance No. 26, Series of 1914, do not permit the Water Company to earn for the use of its property such compensation as is fair to it and to the city and that the enforcement of said Ordinance will result in the

217 taking of the use of said property without just compensation.

W. J. CHINN,
Special Master.

October 5th, 1915.
Denver, Colorado.

218 In the District Court of the United States for the District of Colorado.

In Equity. No. 6274.

THE DENVER UNION WATER COMPANY, a Corporation, Complainant,
vs.
THE CITY AND COUNTY OF DENVER, et al., Defendants.

Exhibit A of Report of Special Master.

1914.

On May 21st, at a meeting with the Solicitors of the respective parties, June 3rd was assigned for the beginning of the hearing of the testimony herein.

The testimony was heard on the following days:

June, 3, 4, 5, 8, 9, 10, 11, 12, 15, 16, 17, 18, 19, 22, 23, 24, 29, 30.

(June 4th was given up to an inspection of the Company's plant in and near Denver by the Counsel, Special Master and many of the witnesses.)

July, 1, 2, 3, 6, 7, 8, 13, 14, 15, 16, 20, 21, 22.

August, 18, 19, 20, 21, 24, 25, 26, 27, 28, 31.

September, 1, 2, 15, 16, 17, 18, 21, 22, 23, 24, 25, 28, 29, 30.

September 10 and 11, at the request of Complainant, I used for a journey to Lake Cheesman with counsel representing each party hereto.

219 October, 1, 2, 5, 6, 7, 8, 9, 12, (met but no evidence heard) 14, 15, 16, 19, 20, 21, 22, 23, 26, 27, 28, 29, 30.

November, 2, 3, 4, 5, 6, 10, 11, 12, 13, 17, 18, 19, 30.

December, 1, 3, 7, 8, 9, 10, 11, 12, ,4, 15, 16, 17, 18, 19.

1915.

January, 5, 6, 7, 8, 9, 11, 12, 13, 14, 15, 16,

March, 1, 2.

The arguments of counsel were heard on March 3, 4, 5, 6, 8, 9, 10, 11, 12, 13.

The parties filed with me the printed arguments hereinafter mentioned. I took the entire record, together with the briefs, to California and studied the record and briefs from about April 10th to July 1st, devoting fifty-six (56) days to this work. After returning from California I have devoted probably at least fifteen (15) days to the preparing of this Report.

The following printed documents were filed with me:

Abstract of the testimony prepared by counsel for Complainant, consisting of 901 pages bound in three volumes,

Argument for Complainant containing 666 pages,

Argument for the City by the City Attorney containing 229 pages,

Argument for the Public Utilities Commission by Mr. Nye—134 pages,

Argument in Rebuttal for Complainant—109 pages.

All these documents are returned with this Report.

The testimony for Complainant is contained in eight (8) volumes, numbered 1 to 8 inclusive and marked "Testimony for Complainant." These volumes contain 3882 pages. Defendants' testimony, consisting of 4356 pages, is contained in seven (7) volumes, marked 1 to 7 inclusive, "Defendants' Testimony."

220 The Exhibits offered on the hearing are identified as set out in the report of the testimony and are returned with this Report.

Letters from Counsel of the parties containing additional arguments and citation of authorities, were received by me and are herewith returned, as follows:

Letter dated July 8, 1915, from Hughes & Dorsey.
" " Aug. 13, 1915, from Nye & Marsh.
" " Sept. 7, 1915, " Hughes & Dorsey.
" " Sept. 17, 1915, " Nye & Marsh.
" " Sept. 24, 1915, " Nye & Marsh.

THE DENVER UNION WATER COMPANY, Plaintiff,
vs.
THE CITY AND COUNTY OF DENVER et al., Defendants.

Abstract of Testimony Taken Before W. J. Chinn, Special Master in Chancery for the United States Court in and for the District of Colorado, in the Proceeding Entitled "The Denver Union Water Company, a Corporation, vs. The City and County of Denver, a Corporation, et al., in Equity No. 6274."

Abstract of Testimony of Complainant.

Appearance by counsel.

Argument over Sen. Patterson's request for order permitting audit of company's books.

Witness WILBER F. HAWES.

Direct examination.

By Mr. Hughes.

Am assistant engineer and chief draughtsman of D. U. W. Co., since 1894. Have been connected with it or predecessors since 1890, in same capacity. Am familiar with water system as existed
222 in 1890 and prior thereto. Have had charge of plans, estimates, details of construction and operation of distribution system, including supplying construction crews with plans for pipe laying. Since my connection with company all has been work based on plans given out through my office.

Identifies "Exhibit A", large map showing pipe system, hydrants, etc. in City and County of Denver. Scale, 300 ft. to inch. As to streets, subdivisions, boundaries, etc., prepared from official city maps. Explanation of legend of map. Pipe lines now owned and operated by D. U. W. Co. shown in red, yellow, brown and blue lines, solid or dash. Lines owned by City of Denver, by green lines, solid or dash. Map shows also pumping stations, reservoirs, stand pipes and other works owned by D. U. W. Co. in City of Denver. In 1890 Denver Water Co. obtained supply from two sources—Cherry Creek, five miles from city, and Mississippi Street galleries, three miles from city. Cherry Creek supply distributed by gravity from Capitol Hill reservoir; Mississippi Street supply by pumps at West Denver station. Original source of water supply for Denver was located at 15th St. on Platte River, distributed by pumps from station at 15th and Bassett St. Present Capitol Hill reservoir was used in connection with original supply from Cherry Creek. Moun-

tain Water Co. and Beaver Brook Water Co., in 1890, supplied part of North Denver and Town of Barnum from pump station located at W. 7th Ave. and Platte River. Those systems are now part of D. U. W. Co. system. Pump station and sources of supply abandoned, I think, in 1894.

When property of Citizens Water Company became merged into present plant in 1894, it added three additional sources of supply—through conduit No. 1 by infiltration from Platte Canon filter galleries, and through Conduit No. 2 by mechanically filtered water from Platte Canon and Marston Lake—water from Marston Lake being supplied from Bear Creek. Total mileage of pipe in system when all companies merged in 1894, was 423 miles.

Identifies "Exhibit B", showing water supply system located outside City of Denver—reservoir sites, diverting works, filter plants, supply conduits, etc., with time of construction of different pipe lines. Foundation of map prepared from official maps in U. S. Surveyor General's office. (Description of routes of various lines.) Definition of other colorings on map indicating lands and other works owned either by D. U. W. Co. or South Platte Canal & Res. Co. Words "Mountain", "Bear Creek", "City", and "Cherry Creek" divisions on map indicate arbitrary divisions in the plant for convenience in operation, each in charge of a superintendent. Exhibits A and B together show water system from farthest source of supply to a point of delivery. (Statement of various classes of pipe involved in construction of different conduit lines.) Total mileage of distributing pipe and conduits in system October 31, 1913, 532.45 miles.

223

Printed sheets tabulating. Mains, valves, hydrants and specials in distribution system, Congressional Grant District. Printed sheets tabulating, Mains, valves, hydrants and specials in distribution system, District East of Broadway. Printed sheets tabulating. Mains, valves, hydrants and specials in distribution system, District West of Broadway. Printed sheets tabulating. Mains, valves, hydrants and specials in distribution system, Arapahoe and Jefferson Counties. Statement of special regulating valves, check valves, Smith fittings, and wrought iron pipe fittings, etc., in whole distribution system.

These valves and specials are all a part of the distribution system. Printed statement, summarizing lengths, sizes and weights of mains and hydrant branches in all districts. Printed statement summarizing length of mains, and hydrant branches in the various districts by districts; date of laying and age of various classes and sizes of pipe in distribution system. Printed statement showing tonnage of pipe laid by years and average weight and age. Printed statement showing tonnage of pipe laid by years and average weight and age for Congressional Grant District. Same for District East of Broadway, same for District West of Broadway, and same for Arapahoe and Jefferson Counties. Printed statement showing number and size of valves in system and number of fire hydrants installed by years, divided in districts as above. Statement of length and size of mains laid under pavements and classification of pavements under which

laid in various districts. Printed statement showing pipe laid under and parallel with or crossing railway tracks.

Printed statement showing length, size and character of pipe removed, abandoned, or replaced in the system. Length and size by years of additions to distribution system from appraisal of 1907 to October 31, 1913. Aggregate 46.589 miles. Additions to conduits aggregate 27.55 miles. Records of the water supplied through the system of the D. U. W. Co. are kept in my department under my jurisdiction. They are telephoned in each day from the places from which measurements are made, tabulated and compiled by a clerk and entered in a permanent record. Water supplied from Platte Canon and Bear Creek is measured by meters at Wynetka. From Cherry Creek by a weir at Capitol Hill Reservoir and from the Mississippi Street Galleries by the record of the pumps at
224 the West Denver Station.

Water pumped at Capitol Hill, University Park, Montclair and Ashland Avenue Pump Stations is recorded but not included in daily supply as that is already in original measurements. Printed statements showing consumption of water in Denver from 1876 to 1913 in total gallons, gallons per capita, also record of rainfall and estimated population in the city and a statement of the amount of water pumped in the various pumping stations in the years 1912-13, in million gallons daily. Statements show measurements of maximum and minimum and average daily consumption but do not show the maximum and minimum rates at different hours per day. The figures given concerning lengths of mains and number of hydrants as shown on Exhibit A do not include mains and hydrants owned by the City of Denver.

Cross-examination by Mr. Nye.

Part of the pipe indicated on Exhibit A as having been removed was entirely abandoned and part of it was taken up and relaid elsewhere. I believe that I can compile a statement showing the amount of the pipe that was taken up and relaid. But cannot show exactly where it was relaid. It having been taken to the pipe yard and redistributed as needed without exact record as to whether it was old or new pipe.

The D. U. W. Co. furnishes water outside of the City of Denver to towns of Edgewater, Sheridan, Englewood and Aurora and to some consumers in Jefferson county not in any incorporated town. The amount of water so furnished is included in total consumption records, except that which is taken before the water reaches the measuring station at Wynetka. I have no way of distinguishing water furnished those consumers and the water furnished in the City of Denver. In the water consumption records, years 1890 to 1894 are not included because the record of water furnished by the Citizens Water Company in that period is incomplete. In making up the statement of pipe mileage I have not considered whether the ppipes were owned by the Denver Union Water Company or by the South Platte Canal and Reservoir Company but have taken them as one system.

I have no data giving loss of water by leakage from conduits or mains. I have maps and records in the office showing the length and size of mains laid by predecessor companies of the D. U. W. Co. These have been verified as to size and location by the D. U. W. Co. in making connections with them. I can either furnish copies of these maps or produce originals for examination. The lines of the Citizens Water Company generally paralleled the lines of the American Water Works Company which included the plants of
225 the old Denver Water Company and the other predecessor companies that had been merged into the American Water Works Company. I can prepare a statement showing the extent of those parallel lines. Some of the parallel lines then installed are still a part of the system of the D. U. W. Co. and in use mainly in the congested district between 13th and 20th Streets and Broadway and Wazee Sts. Pressure Gauges are maintained on the system only at the office and at the different pumping stations. I have made no estimate of the pressure maintained at different points on the system or of leakage in the mains or conduits. I believe such estimate was made by the engineers of the Public Utilities Commission this past winter and think we have a copy of it.

The records in my office do not show the weight of pipe laid by the Citizens Water Company. The D. U. W. Co. has always laid what is known as Class "B" pipe.

Redirect examination by Mr. Dorsey:

Compared with the total quantity of water furnished I believe that the amount of water supplied to consumers outside of the City of Denver would be exceedingly small. Company records that would supply this information are not in my department. None of the wooden pipe in the distribution system of predecessors of the D. U. W. Co. now remains in the distribution system. It has all been replaced by cast iron. There have been no changes in the pipe mileage since Oct. 31, 1913. Four or five additional fire hydrants have been set.

The only loss of water that could occur from the mains or conduits would be in the case of breaks or leaks which would be repaired as soon as possible after they were reported. Any leak that continued for any length of time would be evidenced on the surface of the ground. Loss from such causes could not occur to any great extent. A very large proportion of the water furnished the City is measured at Wynetka. Quantities measured at Cherry Creek and West Denver Pump Station represent 1/5 or ¼ of the total supply. Any error in measuring due to slippage would apply only to the water measured at West Denver Station. There is very little variation or irregularity in the flow of water over the weir on the Cherry Creek Conduit, the concrete well behind the weir operating as a quieting box. In using the term merger in connection with the operations of the companies in 1894 I only meant to imply the purchase of the works of the other companies by the D. U. W. Co. which was organized in that year. The Citizens Water Company began to furnish water either in the latter part of 1890 or be-

ginning of 1891. It continued extending its distributing system until 1894. It did not cover all of the ground covered by
226 the American Water Works Company. Duplication of mains occurring from the construction of the Citizens Water company system does not now exist as in 1894. Most of the duplication now existing is in the congested district where the two systems were interconnected to furnish better service. On checking up my records I find that an allowance of 2 to 3 per cent is made for pump slippage at the West Denver Station. The water system in Denver is mainly a gravity system. Any of the pipe laid by the Citizens Water Company and the Denver Water Company and taken up and relaid would appear in the records of the company from the date at which it was relaid. Changes of their pipes were being made for a period of about six years after 1894. Printed statements showing the draft of water in cubic feet per second from the different sources of supply of the D. U. W. Co. Measurements from which these tables are made are taken by the men in charge of the different divisions and sent into the office in the regular course of business.

Recross-examination by Mr. Patterson:

I began to work for the D. U. W. Co. when it was first organized in 1894. Prior to that I was employed by the American Water Works Company and the American Water Works Construction Company. I think the 423 miles of pipe that I stated composed the system in 1894 was after the consolidation and included the conduits from Platte Canon, aggregating between 40 and 50 miles. I do not remember and would not attempt to state until I have tabulated it, the amount of pipe laid by predecessors of the D. U. W. Co. which was taken up and relaid since 1894. I think the records in my office show two locations where the water mains are bonded to the street railway tracks. I don't remember just when the Citizen's Water Company began to supply water, whether its system was to begin to supply water and seek consumers as rapidly as part of its system were completed. The parallel mains that were taken up were not taken up and discarded but were taken up, as new mains were needed and relaid elsewhere.

Recross-examination by Mr. Nye:

I do not know of any estimates by Mr. Prince of the weights of pipe laid by predecessors of the D. U. W. Co. I don't know of any pipes being laid to carry leakage from wooden mains to storm sewers. Part of the water furnished the system from the Capitol Hill reservoir is furnished by gravity and part is pumped into the high service district by the Capitol Hill Pump Station which furnishes water as far east as Aurora. The distributing pipes in the town of Aurora are owned by the town. We have never
227 made any estimate of the loss of water by evaporation from distributing reservoirs. The Capitol Hill Reservoir, and Ashland Avenue reservoir are both directly connected with the

pipe lines that pass Wynetka. The West Denver Pump Station pumps directly into the mains at West Denver. I think it is used every day but not to the same extent. I have a record in the office showing day by day the operations at each of the pumping stations, and will produce same.

Redirect examination by Mr. Dorsey:

The distributing reservoirs in the City are covered. Covering a reservoir does not affect evaporation from it.

Witness WILBER F. HAWES, recalled.

Direct examination by Mr. Dorsey:

Pages 532-584 Exhibit C, contain detailed statements of street mains of the D. U. W. Co. size, character of material, when laid and length in feet, subdivided between the Congressional Grant District, District East of Broadway, District West of Broadway, and Jefferson and Arapahoe Counties. Offered and admitted as witness' testimony. Since I was last on the stand about 500 feet of 6 inch pipe has been removed from the system at the Civic Center site. No new pipe has been laid. Pages 585-638 of Exhibit C, contain complete statement of specials in mains in the distribution system. Offered and admitted as witness' testimony. Pages 639-677 Exhibit C, contain a complete statement of the valves in distributing mains, their location, number and size. Offered and admitted. Pages 678-705 Exhibit C, contains a complete statement by districts as heretofore described of the fire hydrants in the system together with pipe and specials required for their installation. Offered and admitted. Page 705 of Exhibit C, contains a list of Smith valves and specials in the system and all pressure regulating and check valves. Offered and admitted.

Pages 708-709 of Exhibit C, contains a list of valve vaults in distribution system showing masonry contents, etc. Offered and admitted. Pages 710-758 Exhibit C, contains a statement in detail of pipe laid under pavement and under parking. Offered and admitted. Pages 759-762 contain a statement of corrections of errors to be applied to quantities involved in distribution system, pavements, etc. Offered and admitted. Pages 763-799 Exhibit C contain statement of pipe under steam and street railroad track. Offered and admitted. Pages 800-808 of Exhibit C, contain statement of cast iron pipe taken out of the system. Offered and ad-
228 mitted. Pages 809-810 of Exhibit C, contain statement of cast iron pipe abandoned. Offered and admitted. Pages 810-811 of Exhibit C. Contain statement of wood pipe taken out or abandoned. Offered and admitted. Pages 812-814 Exhibit C, contain statement of cast iron pipe laid to replace cast iron pipe taken out or abandoned. Offered and admitted. Pages 814-815 Exhibit C, contain statement of cast iron pipe laid to replace wood pipe taken out or abandoned. Offered and admitted.

Pages 24 and 25 Exhibit C contain tables showing run off of water in cubic feet per second per square mile on the south fork of

the South Platte above Lake Cheesman. Offered and admitted. Pages 26 and 27 Exhibit C, contain tables showing net stream flow of the South Platte Canon, drainage area 2,688 square miles. Offered and admitted. Page 28 contains table showing the stream flow in cubic feet per second of Bear Creek above Morrison, drainage area 172 square miles. Offered and admitted. Mr. Nye admits that the stream flow records as measured by the D. U. W. Co. are used by the State Engineer and constitute the official record for the flow of the streams at the points designated.

When the D. U. W. Co. was organized in 1894 it took over in the pipe systems of the predecessor companies the following mileage. American Water Works Company system 235.184 miles of mains; 10.435 miles of conduits; total, 245.619 miles. Beaver Brook and Mountain Water System, 40.837 miles. Citizens Water Company, mains, 97.711 miles; conduits, 44.860 miles; total, 142.571. The total mileage of mains—373.732 miles. Conduits—55.295 miles. Grand total 429.027 miles. Since this time, 34.709 miles of the Citizens Water Company mains have been taken up and 0.067 miles abandoned. .1965 miles of conduits laid by the Citizens Water Company have been taken out or abandoned, leaving 105.830 miles of the system of the Citizens Water Company in the present system. At the time of the organization of the D. U. W. Co. there was about 83 miles of parallel main in the distribution system.

Exhibit W. admitted.

Explanations of the additions to the plant of the D. U. W. Co. from the appraisal in 1907 to Oct. 31, 1913, as set forth in Exhibit Z.

Cross-examination by Mr. Nye:

There is no duplication in the items set forth in Exhibit C from pages 532-815. The A. P. Smith fittings and valves are specially designed to permit of connections with the system while under pressure, and once used for that purpose they remain as part of the system. I do not attempt to testify as to the cost or value
229 of additions shown by Exhibit Z, but only as to the facts concerning the additions.

Witness HARRY I. DEBERARD.

Direct examination by Mr. Dorsey:

I am and since 1899 have been chemist and bacteriologist for the D. U. W. Co., obtained technical training at Beloit College, Wisconsin, and Chicago University. Have been employed by the D. U. W. Co. since graduation. The Water company maintains a laboratory for the purpose of keeping track of the character of the water furnished the City. All of the water supplied to the city is filtered either by infiltration, English Slow Sand or Mechanical filtration processes. There are three infiltration plants, one at Platte Canon, one at Mississippi Street on the Platte River, and one on Cherry Creek. One English Slow Sand filter plant at Platte Canon, one Mechanical plant near Platte Canon, and one at Marston Lake.

All water furnished by the company has been filtered ever since my connection with it. (Description of Methods of filtration.) I make tests to determine the condition both before and after filtration. For the purpose of these tests samples of the water are taken at each of the plants in sterilized bottles, which I receive personally at the express office, take to the laboratory and subject to the processes necessary to make the determinations and obtain the information desired. Samples are taken of the river water, of the water in the sedimentation reservoirs, at the filter plants, from the conduits at Wynetka, from Cherry Creek and Mississippi Street conduits and from distribution pipe system in the city. The laboratory is adequately equipped. In addition to the filtration processes there are installed sterilization plants where the water subsequent to filtration is treated with sterilizing chemicals. The water furnished is pure and healthful. I consider the Denver water to be as pure or purer than in any city of like size, or larger, in the country. The D. U. W. Co. takes the utmost precautions to purify the water. It also employs men to patrol and inspect the water sheds above its sources of supply to prevent contamination before its water is taken. The water shed immediately surrounding Lake Cheesman is carefully fenced to prevent any direct contamination of that supply. Pages 52-61 Exhibit C correctly set forth the result of various analyses and investigations of the conditions of the water from the various supplies and filters. This water contains no chemical properties that are deleterious to health. Plates numbered 8 to 17 are
230 diagrams showing the turbidity and bacterial contents of the water prior to and after filtration for the fiscal year 1913. Samples were taken on the dates indicated by the perpendicular lines on the plates and the height of the lines corresponding with the scale shows the result of the examination of those samples. Special examination is made to determine the presence of bacillus coli. It is generally or frequently present in the raw water but practically absent after purification and filtration. By the use of the sterilizing treatment all of the coli group of bacteria are exterminated. The Typhoid germ is the most easily killed by this treatment. Plate number 20 in Exhibit C shows graphically the death rate from typhoid fever in Denver per 100,000 since 1887.

Cross-examination by Mr. Nye:

The first year I was with the company I was assistant to Prof. E. G. Smith, of Beloit College, Consulting Chemist. I do not recall any particular changes in the method of filtration since I came with the company. The Slow Sand filters which were put into operation in 1901 were an additional construction constituting no formal change in the method of filtration. They simply augmented the supply of filtered water. Marston Lake is a sedimentation, storage and distributing reservoir and the water from it is all filtered after it passes the lake. A leak in a main shows an increase in bacteria in the water in the main. There has been more than one occasion when a leak in a conduit has been evidenced by such an increase, but they have not been frequent. If any of the filters should cease

to perform the duty for which they are intended, such failure would be evidenced by an increase in bacteria which I could detect in the laboratory. It would not be manifest if a sterilizing agent were employed. I also make tests to determine the hardness in the water. There is a variation of the degree of hardness from the different sources of supply. The Mississippi Street water is the hardest, Marston lake water is the softest. Water from Soda Lakes has nothing to do with that. There is a very slight increase in the permanent hardness of the water due to the use of the Coagulant in the filtration. There is more chlorine in the water from south fork of the South Platte than in the water from the north fork. The organic matters found in the water are entirely removed by sedimentation and filtration. Tests are made with each sample to determine the presence of organic matter in the water. The sterilizing process itself destroys the bacteria, the filters remove the organic matter and mud and silt that may be in the applied water, acting as a strainer and effect the organic and inorganic matter simultaneously. The water after being filtered does not contain a trace of the chemical used as a coagulant. The water company has made no effort to get rid of the hardness in its water supply because it is not pres-
231 ent in such amount as to warrant any effort in that direction.

I would consider a reasonably hard water better than soft water for domestic purposes. I do not believe that the supply of the D. U. W. Co. would be any better if it was not so hard as it is. I do not know of any complaints having been made as to the hardness of the water supply. It would be possible to reduce the degree of hardness but it would be an expensive process and it could not be used with the present processes of filtration without considerable re-construction.

Chlorines have to do with the incrustations in the water. The water from Marston Lake is a little softer than the other supplies because it is supplied from Bear Creek. The water is not as hard as the water from Platte River though the water from the north fork of the Platte is softer than Bear Creek. The water from the North Fork however is mixed with the water from the South fork. The fencing of Lake Cheesman keeps out immediate contamination of that water supply from animals, human beings, etc. The water before reaching and after passing through Lake Cheesman flows in the natural channel of the stream which is not fenced but which is protected by inspection and patrol. Even with these sources of pollution I think there is an advantage in the fencing of Lake Cheesman. Sulphate of copper is used to obliterate algae growths that might be obnoxious as producers of odors. Alum is used as a coagulant in the mechanical filtration process. Hypochlorite of lime is used as a sterilizing agent but it has not been found necessary to use it at all times. The typhoid group of bacilli are different from the coli group. The typhoid must come from the excheta of human beings. The removal of the colon bacilli however is necessarily accompanied by the removal of the typhoid bacilli. Tests for typhoid is not positive so we use the test for coli as an index of removal of the typhoid. Colon bacteria occurs in about 60% of

the raw water samples. Occurs about as frequently in the Bear Creek supply as in the Platte reservoir supply.

Redirect examination by Mr. Dorsey:

The water from Cherry Creek and the Mississippi Street galleries are analyzed less frequently than the other supplies because they are more uniform. This practice results from our experience in handling these waters. I think our tests are of a character to keep us constantly informed as to whether the filters are properly operated and performing their office. Moderately hard waters are considered better than very soft waters. Water of the degree of hardness as this water may require a slight increase in the consumption of soap.

232 This water is used in large quantities for steam boiler purposes by railroads and stationary plants. The operation of these boilers has been carried on successfully. The methods used in the treatment of this water supply are the improved and modern methods. The mechanical filters have been installed for a number of years but they are as efficient as any in the country. There is considerably greater necessity for fencing a body of deep standing water to prevent bodies of animals, etc., from falling into it than is the case of shallow flowing streams above and below Lake Cheesman. Typhoid bacillus is never present except when the colon bacillus is present. When you remove the colon bacillus from the water you are able to say with safety that the typhoid bacillus is also removed.

Recross-examination by Mr. Nye:

Approximately 99 per cent of the harmful bacteria are removed from the water by the process of treatment. We have removed as high as 99.9 per cent of all bacteria. I would not say that the Colorado Springs water supply is any purer bacteriologically than Denver supply or as pure. I would not say that it was as good a supply as Denver. I do not think that they filter the supply and it might be subject to serious pollution at times. The mechanical filter plants of the company are about 21 years old. They are not inadequate. They are as efficient now as they ever have been and I know of no other more efficient filters on the market. It is not necessarily true that clogging of a mechanical filter increases the bacteria by affording a culture medium.

Redirect examination by Mr. Dorsey:

I consider the efficiency of the filters of the D. U. W. Co. equal to the filters in any city.

Recross-examination by Mr. Nye:

The combination of the right amount of sterilizing agent and an efficient plant brings about the highest removal of bacteria coupled with the best quality of effluent. And that is what we have in this case.

Witness DAVID G. THOMAS.

Direct examination by Mr. Dorsey:

I am Chief engineer and General Superintendent of the D. U. W. Co. Been connected with the company or its predecessors about 25 years, the last 6 or 7 years as Chief Engineer, of the
233 company. Description of water system. Method of treating, distributing and measuring the water supply to the city. The plant of the D. U. W. Co. consists of storage reservoirs, filter plants, and distributing system. Lake Cheesman, capacity 26 billion gallons, 48 miles from the city. Marston Lake 6,400,000,000 gallons, 4 miles from city. The principal intake works are located in Platte Canon 23 miles from the city where a concrete dam and intake chamber diverts water into a 60 inch conduit which carries the supply to Marston Lake, 13 miles distant, to the Platte Canon Reservoir 3 miles distant. At Platte Canon is located a slow sand filter plant and sedimentation basins where the water settled in the Platte Canon Reservoir is purified. At Willard, two miles below Platte Canon, is a mechanical filter plant which furnishes an additional method of purifying the settled water from Platte Canon Reservoir. Water from the Slow Sand filter plant is conveyed to the city through a 40 inch conduit terminating at the Ashland Avenue Reservoir on the north side. Water from the Willard Filter Plant is conveyed to the city through a 34 inch conduit terminating at Capitol Hill Reservoir. At Platte Canon is also located an infiltration plant taking the ground water supply at a depth of about 15 feet which is conveyed to the city through a 30 inch conduit terminating at the Ashland Avenue Reservoir. Marston Lake in addition to receiving a supply of water from Platte Canon receives a supply from Bear Creek through the Harriman Ditch and flume, diverting at a point above Morrison. Water from Marston Lake is treated in a mechanical filter plant and conveyed to the city through a 48 inch conduit terminating at the Capitol Hill Reservoir. All of the water from Platte Canon and Marston Lake is measured by Venturi meters at Wynetka about 1 mile west of Littleton. At this point all of the conduits are interconnected so that water may be transferred from one to another in event of breaks above or below that point. On Cherry Creek near Sullivan, 6 miles from the city is located another infiltration system. The water from which is conveyed to the city through a 36 inch and 30 inch conduit terminating at the Capitol Hill Reservoir. At Mississippi Avenue on the Platte River is located another infiltration system. Water from which is conveyed to the West Denver Pumping Station through a 40 inch and 48 inch conduit. The water from Platte Canon, Marston Lake and Cherry Creek is distributed to the greater part of the city by gravity pressure from the Ashland and Capitol Hill Reservoirs. The water from Mississippi Street is forced into the distributing system by the pumps at the West Denver Pumping Station which operate against the head created by the Capitol Hill
234 reservoirs. In addition to the gravity system there are 3 high pumping services, embracing territory lying at an eleva-

tion too great to be properly served by gravity pressure. The pumping station at West 29th Av. and Sheridan Boulevard supplies the high territory in the northwest portion of the city. The pumping station at the Capitol Hill Reservoir supplies the Higher portion of Capitol Hill and Park Hill, Montclair and Aurora. The pressure in Montclair and Aurora being supplemented by a booster station located at 26th Avenue and Monaco St. A pumping station at South University and Jewell Ave. supplies the high lying territory in the South eastern portion of the city. Water from these reservoirs and pumping stations is delivered to the consumers through large cast iron mains occupying various streets in the city. The water is served to consumers at a good domestic pressure. For our information that we may know that good pressure is being supplied we maintain pressure gauges at each of the pumping stations and keep and record the elevation of water in the different reservoirs and know from the pressure on the pumps and the height of water in the reservoirs generally what the pressure is in different parts of the city. The devices provided for measuring water are accurate and approved devices. The weir at the Capitol Hill reservoir over which water from the Cherry Creek is measured is calibrated and a flow table takes into consideration all variations in velocities that might occur at different heights over the weir. We have made no allowance for leakage after water passes the measuring devices because if any leaks were present it would be apparent on the surface of the ground immediately and it would be reported and repaired. There is no appreciable evaporation from covered reservoirs.

Some water is supplied to consumers outside of the city of Denver. I should say that 3 per cent would be the outside limit of consumption outside the City of Denver. Table of comparative elevations herewith submitted shows the elevation of various working points of the water system above city datum. Plate No. 5 shows the catchment basin of the South Platte River above Denver. Sheets numbered 22 and 23 show the elevations of water in Marston Lake from 1903-1913 with computations as to evaporation from the surface thereof. Sheet numbered 40 shows the amount of water pumped in the different stations of the D. U. W. Co. for 1912-1913. Sheet Numbered 51 shows the amount of water supplied by the D. U. W. Co. from the different sources. Plates 21-35 show details relating to the construction of wood pipe conduits as done by the D. U. W. Co. Plates indicate character of trenching and different size pipe, number and size of staves, size and construction of bands and shoes, and tables for band spacing according to pressure.

235 Cross-examination by Mr. Nye:

Sedimentation basins above the slow sand filters at Platte Canon are used in the event of interruption of supply to the Platte Canon reservoir and also furnish additional process of sedimentation to supplement the work of the Platte Canon reservoir, when the reservoir water is unusually turbid.

These sedimentation basins add much to the sedimentation efficiency at Platte Canon. There are three filtered water conduits and

one infiltration conduit passing Wynetka. They are interconnected. The 30 inch conduit and 40 inch conduit from Platte Canon, the 34 inch conduit from Willard filters and the 48 inch conduit from the Marston Lake filter plant.

We have made some experiments, but on a small scale, to determine the evaporation from the covered distributing reservoirs and found that it was negligible.

I estimate that the quantity of water furnished outside the city limits of Denver is not more than 3 per cent of the whole supply. From my knowledge of the amount of water pumped to Aurora and Montclair by the booster station at 26th Avenue and Monaco Street, by comparing populations of Aurora and Montclair with the other territories in which we supply water I venture to say that 3 per cent is high.

Cross-examination by Mr. Patterson:

In the figures relating to the quantity of water pumped at the various stations the pressure against which this water is pumped has no bearing upon the quantity. Quantity is determined by the displacement of the pump and the number of revolutions. Pressure simply indicates the pressure at which water was discharged. The maximum pressure at the Union Depot has been about 85 pounds for a great many years.

(Argument by Counsel, as to pressure decision reported in 41st Colorado.) A large pipe under small pressure will furnish more water than a small pipe under large pressure. Pressure is one of the important elements in a water supply but it is not the only element. There are places in the City of Denver where water discharged through 500 or 600 feet of fire hose will not reach the top of a two-story building. The Mississippi Street Galleries are built in the sands immediately adjacent to the river, about 20 feet below the surface of the ground and are always filled with water. There are manholes extending to the surface of the ground through which the galleries may be entered. The galleries were built in 1880 or 1881. It is the flow through the sands horizontally that supplies the water for the galleries. The Cherry Creek Galleries are similarly constructed except they are built of concrete pipe instead of wooden crib. We know that when water stands at an elevation of 216
236 or over at the Capitol Hill Reservoir that we are furnishing a good serviceable pressure. If the water will not flow in a bath room on the second story of the house when the water is being used to sprinkle the lawn it is because the pipe leading to the house is too small. The architect, plumber or man who owns the house is responsible and not the water company.

I know of no surveys having been made with a view to furnishing a complete gravity supply for the city from Sullivan reservoir. Surveys were made for a pipe line to bring water from Cheesman reservoir to Sullivan reservoir from which part of the city could be supplied by gravity. It would not be as economical to supply water to Dnver with a complete gravity system as with the present combined pump and gravity system. The interest charges on a

conduit from Lake Cheesman to Sullivan would exceed the cost of operating the pumping stations. I estimated the cost of that conduit at about three million dollars. The Cheesman-Sullivan survey was made 5 or 6 years ago. If that line was constructed it would not do away with Marston Lake.

Cross-examination by Mr. Nye:

Static pressure is the dead pressure on a pipe due to the height of water standing above the point at which pressure measurement is made. The static pressure is reduced in the pipe when water is drawn from it. There is no formula that I know of by which the exact reduction over the entire system could be determined by the relationship of the number of taps or consumers to the water supply. It is not true that during the irrigation hours water pressure in the downtown district is insufficient for fire protection. In certan sections of South Denver where the distributing pipes are owned by the city that is true. It is not true in the Capitol Hill district. It is not true in Globeville. The 4 inch pipes in Globeville are only laterals to the main supply. In South Denver there are long lines of 4 inch pipes unsupported. Every summer we test pressures on different parts of the system to determine whether there is a necessity for increasing the supply of water in those sections to take care of additional consumption that may be incurred. The pressure maintained at the Water Company's office is about 65 pounds and at the West Denver Pump station about 85 pounds. It varies between these points and over the city according to variation in elevation. What we refer to as the low service is the gravity service from the Capitol Hill and Ashland Ave. reservoirs and low refers to the elevation and not to pressure. What we refer to as the high service is the pumping districts in different sections of the city. Along Colfax Avenue the dividing line between the high and low
237 service is at about Corona Street. The highest pressure on the system is about 100 pounds that occurring in Park Hill and out toward the Stockyards.

Redirect examination by Mr. Dorsey:

There have been practically no changes in the system since October 31, 1913. An additional boiler feed pump has been installed at Capitol Hill station and half a dozen fire hydrants have been placed. The stock of materials on hand is practically the same. For 15 consecutive days during the summer of 1913 the average daily consumption of water was 70 million gallons and upwards. During certain hours of the day water was furnished at a much greater rate than that. The plant must therefore be equipped to carry that peak load.

Exhibit A. shows accurately the distribution system of Denver as it exists today. We are not dependent for the information there shown upon the records of the predecessor companies. We have made connections to all of the mains in the system since the formation of the D. U. W. Co. and know from observation that the mains are as they are indicated. The capacity of the Platte Canon Reser-

voir is 300 million gallons. Marston Lake 6,400,000,000. The sedimentation basins at the Platte Canon Filters are necessary to augment the efficiency of the sedimentation when the river water is highly turbid. This is because the water has not as long a time to settle in the smaller reservoir at Platte Canon as it has in the large reservoir at Marston Lake. Sedimentation depends entirely upon the time that the water remains in a reservoir. The city of Denver has always been equipped with fire engines for extinguishing fires. The water system has always been operated with the understanding that fire engines would be used in connection with fires, and the city has equipped itself with fire engines and other fire apparatus with that in view. There are places in Park Hill where fire hydrants are twelve to fifteen hundred feet apart because the city has not authorized the water company to locate hydrants. The company cannot of its own accord install fire hydrants and receive compensation therefor from the city, it must be done by authority and direction of the City. The timber construction in the Mississippi street galleries is the same as originally installed. Timber galleries constructed at Cherry Creek have since their original installation been replaced by the concrete pipe. The timber galleries at Mississippi Street are of rectangular construction and the original installation on Cherry Creek were semi-circular in construction, sand got into the semi-circular water space and blocked it off preventing the flow of water. Nothing of that sort has occurred at the Mississippi Street galleries. The timber construction at Mississippi St. is con-
238 stantly submerged in water which preserves the wood and is in as good a condition today as it was when installed. The service pipes in residences that are at fault, when sufficient water cannot be obtained, are owned, installed and controlled by the owner of the property. And the fault is the fault of the owner of the property and not of the Water Company. The pipes in the distribution system in South Denver that are too small were originally installed by the town of South Denver and now belong to the city of Denver. The new water system being installed in Los Angeles in which a single aqueduct is used to conduct water for a long distance employs large storage reservoirs near the city of Los Angeles, into which the water is delivered by the aqueduct and upon which they would depend for supply in the event of breaks in the aqueduct. The city of Los Angeles also has its present infiltration system which it proposes to keep in service to supply water in event of trouble with the aqueduct. If the theoretical scheme suggested by Senator Patterson for the construction of a single aqueduct from Lake Cheesman to Denver as the sole supply were adopted it would be necessary to install large storage reservoirs in the city or go out of business if anything happened to the aqueduct.

The reservoir now constructed at Sullivan would furnish only about one-half a day's supply, which is insufficient as a safeguard against this condition. With the system as at present operated in Denver there is the safeguard of a large number of conduits and also the Marston Lake reservoir within 3½ miles of the city containing nearly six and one-half billion gallons of water. If the single

aqueduct were constructed it would still be necessary to retain Marston Lake. When we find that there are too many consumers on a main for its capacity we increase the supply by bringing an additional feeder for that main.

Recross-examination by Mr. Nye.

We do not keep the pressure gauge records on file except for the current month in which we are operating because they accumulate to such an extent that we have no room for them. The records are really for a day to day information to indicate to us whether the system is operating normally or whether breaks or unusual drafts occur. We began destroying these records, every month, about a year ago. Previous to that time we let them accumulate for five or six years. I will be glad to preserve those records and future records until the final determination of this case.

My knowledge of the size and location of the distribution mains obtained from inspection in making connections with them
239 checks with the information on the map Exhibit A. The records of the date of laying of the mains by the Denver Water Company and the American Water Works Company are exact, but the records of the dates of laying by some of the other companies were not as well kept. We have the records to show when pipe laid by some of the old companies was taken up, but cannot tell exactly to what point it was transferred in relaying. It was taken to the pipe yard, and after it reached there was regarded as so much pipe on hand without regard to where it came from. The pipe was in good condition when taken up, was cleaned and when relaid was as good as new again. Some was repainted but some did not need it. Some small pipe was abandoned, cut off from the system and left in the streets. The mileage of pipe owned by the Denver Water Company in 1894 was greater than owned by the Citizens Water Company probably one hundred miles greater.

So far as I know the Company has always complied with the directions of the city to install fire hydrants. The understanding as to the use of fire engines by the city for the extinguishment of fires was not contained in any ordinance or contract. It was simply an implied understanding because the fire department was always buying steam fire engines for use in the city. It is good management and good economy to operate fire engines with an abundant water supply to furnish the engines with water. Every large city in the country uses fire engines to put out fires.

When the sedimentation basins above the filters at Platte Canon are being used for a second sedimentation they do only a small portion of the work of sedimentation. There are times when the water in the river is so turbid that we do not attempt to use it at all but shut out the intake and draw the supply from the reservoir until the existing turbidity ceases. It is true that when the turbidity of the water is high the capacity of the sand filters is determined by the capacity of the sedimentation basins to supply them with the character of the water desired. The sedimentation basins above the

filters are not in service now, they were this winter about 2 weeks in January when the ice gorge produced an excessive turbidity. We operated the sedimentation basins last summer, I don't recall for how long. The nominal capacity of the slow sand filters is about thirty million gallons daily. The slow sand filters have been enlarged since the construction of the Platte Canon Reservoir. The water from the sedimentation basins passes to the filters over a weir which acts as a skimmer, taking only the surface water.

The service pipes are own-d and installed by the consumers. The actual service connection with the main is made by the company and the connection furnished by the company at the ex-
240 pense of the consumer. It is not true that on Capitol Hill about the dividing line between the high and low service absence of pressure is noticeable over a considerable area.

If an accident occurred to the 60 inch conduit in Platte Canon the Platte Canon Slow sand filters would be supplied by direct diversion from the river, and the Willard filters from the stored water from the Platte Canon reservoir until repairs could be made, or the pumping plant at Platte Canon would be used to pump the water from the slow sand filters on through the mechanical filters to the city until such time as the repairs could be made. We could do that indefinitely.

I know that it is a fact that the water furnished on the North side of the city at present is very dirty water. There is a break on the conduit from the infiltration plant at Platte Canon. I think we first noticed the break last Friday. The conduit at that point is laid a couple of hundred feet away from the bank of the river but floods in the river has caused it to come out of its banks and up on the land in which the pipe lays.

Redirect examination by Mr. Dorsey:

The point at which the river water is getting into the conduit is about three-quarters of a mile north of the filter plant, at Beans' Farm. The flood in the Platte river at present is very unusual, the water never before had been up to the point where it is now. The flood has done a great deal of other damage along the river. It has covered the roads, washed out bridges and is unprecedented in the last 40 years since records have been kept of the flow in the river. In addition to the intakes at the sedimentation basins and the stored water in the Platte Canon reservoir the High Line Canal could be used to convey water to the Platte Canon Reservoir in the event of a break of the 60 inch conduit. The stored water from Marston Lake could also be made to supplement the supply from Platte Canon.

In destroying the pressure gauge charts we had no design whatever except to dispose of something that was taking up room. The record of the height of water in the reservoirs and the pressure on the pumps at the pumping stations are preserved in the permanent records. These permanent records indicate at all times the pressure on the system. The reservoir capacity of the sedimentation basins

at Platte Canon in no way limits the sedimentation capacity because the water is constantly moving through the basins to the filters.

Recross-examination by Mr. Nye:

The flow in the river today at Platte Canon is about twenty-four to twenty-five hundred feet, which is about seven to eight
241 hundred less than a week ago. The river water is standing now about three feet deep on the ground over the top of the conduit. It would be possible to utilize Marston Lake to supply the normal capacity of any one of the conduits passing Wynetka in addition to the conduit that it normally supplies. The Marston Lake filters are at present operating at about 70 per cent of their capacity. The service pipes are owned and controlled by the property owners. We recommend to the consumer not to put in too large a connection to the main but leave it to his discretion to install as large a service pipe as he desires as a corporation cock will give enough water to furnish a pipe 25 to 50 per cent larger than the hole in the main. We would install an inch connection for a consumer if he were willing to pay for it.

Witness NORMAN REED.

Direct examination by Mr. Dorsey:

Am an electrical engineer, now assistant general manager Colorado Power Co. Formerly chief electrical engineer and superintendent motive power Denver City Tramway Company. Was with the Tramway Company from Sept. 1909 to June 1913. To eliminate electrolysis of the water mains of the D. U. W. Co. these mains are bonded to the tracks of the Denver City Tramway Company at different points where the flow of stray currents indicates danger of electrolysis.

The water pipes are not used as part of the system of the Tramway Company but stray current finds its way on to the pipes and must be taken off to prevent injury. Similar return currents are flowing along the line of the street railway system in the street all the time. There's no danger of shock or disturbance to those using the water service from the pipes. This installation was made before I went with the Tramway Company. The use of this drainage system is very general throughout the country. The telephone company has similar connections between the tracks and its cables. The water system of Globeville, which is owned by the City of Denver, is bonded to the tracks of the tramway company. The work was authorized by the Public Utilities Commission. I conducted the survey for this work myself but the actual work was done after I left the Tramway Company.

Cross-examination by Mr. Nye:

I did not conduct any electrolytic surveys for the Tramway Company except the one in Globeville. Connections were decided on

there at three points. I think it was the right and proper
242 thing to do. Without an artificial bond decomposition takes place where the current leaves the pipe. If it continues long enough and is serious enough it is liable to result in a break in the pipe. Insulated joints at intervals on the pipes probably would be more dangerous than non-insulated joints. The likelihood of pipes picking up stray current depends upon the resistance of the earth and the pipes would be no more liable to pick up stray current where they cross under the track than where they parallel them. It is impossible to entirely eliminate stray currents so the safest and best plan is to control them. The only danger that might occur to the Tramway system from stray currents is the loss of power. I never saw a leak on the pipes caused by the stray currents but was told by the Utilities Commission that a leak had been caused in Globeville. The stray currents are liable to start at a considerable distance from the generating plant.

Redirect examination by Mr. Dorsey:

After going over the matter of the electrolysis in Globeville with the Utilities Commission they authorized the expenditure of a certain sum of money in connection with this bonding. It is the point where the current leaves the pipes, not where it comes on to the pipe that the electrolysis takes place. It is possible that natural soil conditions or conditions other than proximity to a power house may cause the current to leave the pipe. But these locations are found by such surveys as have been made and it is then possible to provide for them by bonding.

Witness FRANK ROBERTON.

Direct examination by Mr. Dorsey:

Am chief clerk to the auditor of the D. U. W. Co. In Oct. 1913 I had personal charge of making the inventory of personal property. Printed pages Numbered 819-872 contain the inventory of the personal property of that class as existing October 31, 1913. I personally went to each of the stations enumerated and with the foreman or employes there went around listing all of the articles found and checked them with the previous years inventory. Pages 819-872 admitted as witness' detailed testimony. Changes are occurring in the amount of material on hand all the time but except as to item numbered 23, being the material at the West Denver store house and yard, no substantial change has taken place since that inventory. A report is made each month by the store keeper of the changes in material on hand at the West Denver yard. (Detailed state-
243 ment by witness of changes in quantities of material on hand at West Denver Store Yard.)

Cross-examination by Mr. Nye:

I would not attempt to make a valuation of these items myself.

Witness ARTHUR L. WATSON.

Direct examination by Mr. Dorsey:

Am purchasing agent and store keeper for the D. U. W. Co. I purchase tools, materials, supplies, etc. I should say that we have more tools on hand now than on Oct. 31, 1913 because we are buying all the time. As to general materials I leave the detail of that to the auditing department, but in passing through the yard the stock looks to me about the same as then.

No cross-examination.

Witness WALTER P. MILLER.

Direct examination by Mr. Dorsey:

Have been Secretary of the D. U. W. Co. since its organization in 1894 and have lived in Colorado 45 years. Was connected with the Citizens Water Company, for 6 or 8 months before the organization of the D. U. W. Co. By profession am an attorney-at-law. Am familiar in a general way with the history of the development of the waterworks system and the various companies from time to time engaged in supplying water in Denver. Printed pages 3-10 are substantially correct as to that history. Diagram on page 3 shows the chain of title of the property passing through the various companies. At the time of its organization the D. U. W. Co. acquired the properties of the American Water Works Company and the Citizens Water Company. The American Water Works Company having previously acquired the property of all the other companies operating and supplying water in the City of Denver except the Citizens Water Company. The stock of the South Platte Canal and Reservoir Company is all owned by the D. U. W. Co. except 7 directors shares. The matter appearing on pages 7 and 8 relating to securities issued by the different companies is an extract from the report of the engineers of the Public Utilities Commission made January 6, 1914. The South Platte Canal and Reservoir Company was organized before the D. U. W. Co. Pages 3-10 admitted as the detailed testimony of the witness.

244 Plate Number 1 is a map of the City and County of Denver reduced from an official large map. Plate Number 2 is a small map containing substantially the same information as Exhibit B. The coloring on Exhibit B indicates the division between the property owned by the D. U. W. Co. and the S. P. C. & R. Co. The S. P. C. & R. Co. generally owning all of the property from the Platte Canon Filter plant south to Lake Cheesman and the D. U. W. Co. owning all property from the filter plant north to and including the City of Denver except conduit No. 7. The D. U. W. Co. has owned the stock of the S. P. C. & R. Co. since June 10, 1899. Exhibit D is certified copy of articles of incorporation of the D. U. W. Co. Exhibit E. is certified copy of articles of incorporation South Platte Canal & Reservoir Company.

In addition to owning the stock of the South Platte Canal & Reservoir Co. the D. U. W. Co. also holds a lease to all of the property of

the S. P. C. & R. Co. Exhibit F. is a copy of the lease of the S. P. C. & R. Co. to the D. U. W. Co. The D. U. W. Co. also guarantees principal and interest on the bonds of the S. P. C. & R. Co.

Am also secretary of the S. P. C. & R. Co. I have charge of the matter of real estate, titles, records, etc., for both companies. Title deeds, etc., are in my custody. Pages 399-413 contain a list of the real estate and rights of way owned by the D. U. W. Co. and the S. P. C. & R. Co. on Oct. 31, 1913. The fee title to these lands stands in these companies except where it is in John Evans and William F. Hayden, Trustees. And one instance in the Littleton Milling and Water Power Company. The stock of which is owned by the D. U. W. Co. The D. U. W. Co. is the beneficial owner of all of the property however. Pages 399-413 admitted as witnesses' detailed testimony. Pages 413-416 contain a list of rights of way and so called water rights owned by the D. U. W. Co. Admitted as the detailed testimony of the witness. Pages 417-427 contain a list and description of lands and subterranean or percolating water rights owned by either the D. U. W. Co. or the S. P. C. & R. Co. Admitted as detailed testimony of the witness.

Direct examination by Mr. Hodges:

Am familiar with the water rights of the D. U. W. Co. and the S. P. C. & R. Co. Exhibit G. is a certified copy of decree of the District Court of Douglas County of the water rights of the Platte Canon Ditch. Offered in evidence, objected to by Defendants on the ground that the D. U. W. Co. and S. P. C. & R. Co. does not and cannot own title covered by these water rights. Admitted
245 subject to this general objection which is understood to apply to all of this proof. Exhibits H to O are certified copies of deeds conveying to the D. U. W. Co. title to lands and the attached water of the Platte Canon Ditch offered subject to general objection. (These deeds cover part of the first enlargement of the Platte Canon Ditch of 34 second feet and the second enlargement of 17.30 second feet as referred to in Exhibit G.) Both of the first appropriations, by construction amounting to 1.56 second feet and enlargement 17.30 second feet are also conveyed by Exhibit L. to Walter S. Cheesman by Phœbe Strong and Charles F. Strong and by Walter S. Cheesman to the D. U. W. Co. Exhibit P. is certified copy of the deed of the Citizens Water Company to the D. U. W. Co. conveying all of the property owned by it, including water rights. Since acquiring its claim to title in the Platte Canon Ditch the Water Company has used said water either for the water supply of the City of Denver or for the irrigation of lands owned by the company under the ditch. It has always used the water for the supply of the City of Denver during the non irrigating season to amount of 56 second feet. Beginning this use in 1889. During the irrigating season it has used the 52.86 feet which it bought for city supply and for irrigation. The Denver City Water Company appropriated 2.50 second feet of water for domestic purposes as of December 20, 1870 by the construction of the first water plant in the City of Denver. The Denver City Irrigation and Water Company appropriated 30 second

feet for domestic purposes as of Sept. 1878 by the construction of the West Denver Pumping station, and by the construction of the Mississippi Street Galleries. The Domestic Water Company appropriated 14.2 second feet for domestic purposes from Cherry Creek by the construction of diverting galleries and the pipe line in 1886. Which water has since been in continuous use except for one year when the pipe line was out of service being repaired. The Citizens Water Company in 1889 appropriated 12.38 second feet of water by the construction of infiltration galleries at Platte Canon and a 30 inch conduit to the City through which the water has since been used continuously. Proceedings for the adjudication of these rights are pending in cause known as No. 559 in the Douglas County District Court. The Citizens Water Company in 1892 appropriated 24.75 second feet by the construction of diverting works and a 34 inch pipe line from these works to the city. This water has since been used continuously. The D. U. W. Co. in 1899 appropriated 38 second feet by the construction of the Slow Sand filter plant and a 40 inch conduit leading from Platte Canon to the City. This water has since been used continuously. Proceedings for the adjudication of
246 these rights are pending in said cause No. 559. in Douglas County. The S. P. C. & R. Co. March 8, 1912 make an appropriation for 120 second feet by the construction of new intake works in Platte Canon and a 60 inch conduit leading to Marston Lake but claims the right as of Oct. 1, 1889 by virtue of a previous filing for a similar diversion by the Citizens Water Company right and title to which was conveyed to the D. U. W. Co. This water has since been used continuously. The D. U. W. Co. also has title to one second foot of water from the High Line Ditch at Platte Canon and for water for 20 acres from the High Line Ditch at Sullivan.

Title to all of the appropriations made by predecessor companies was transferred to the D. U. W. Co. by deed when it acquired the property of those predecessor companies. Exhibit Q is a certified copy of the decree for the water rights of Lake Cheesman granted by the District Court of Park County, State of Colorado. Offered subject to general objection. Exhibit R is certified copy of map and statement of claim for Lake Cheesman filed in the State Engineer's office by the S. P. C. & R. Co. Offered subject to general objection. Exhibit S is an enlarged copy of same.

Cheesman Dam was constructed by the S. P. C. & R. Co. Decree for the water rights was applied for and secured by that company. Water has been used by the D. U. W. Co. under its lease from the S. P. C. & R. Co. The D. U. W. Co. owns 100 out of 400 shares of the Harriman Ditch Company, owner of 4 decreed priorities out of Bear Creek and Turkey Creek amounting to 57.10 second feet. Water obtained under said shares is used by the company through Marston Lake. The water company also has the right to all surplus water carried by said ditch under appropriation of September 21, 1892 for storage and other uses in the irrigation and non-irrigation season. The D. U. W. Co. owns 110 out of 400 shares of the Soda Lakes Reservoir and Mineral Water Company, which has an appropriation for storage water out of Bear Creek claiming priority

as of February 11, 1893. Water obtained under said priority is used by the D. U. W. Co. through Marston Lake. The D. U. W. Co. owns 72 out of 400 shares of the Bergen Ditch and Reservoir Company's appropriation from Turkey Creek, the greater portion of which is not yet decreed. The D. U. W. Co. is the owner of Harriman Lake having an appropriation as of May 1, 1873, of 18.09 second feet and April 3, 1875 of 37.58 second feet.

The original rights for Marston Lake were acquired by the Citizens Water Company and the original rights to Harriman Lake by George W. Harriman but all were transferred to the D. U. W.
247 Co. Water from Marston Lake has been used altogether for city supply. Exhibits T and U are certified copies of decrees by the District Court of Douglas County for the Rough and Ready Ditch and mill rights owned by the Littleton Milling and Water Power Company, the stock of which company is owned by the D. U. W. Co. Exhibits T and U offered and admitted. The Denver Union Water Company is also owner of a decree granted the Denver City Irrigation and Water Company for 278.26 second feet for power purposes for the pumping plant at West Denver, appropriation September 10, 1878. The D. U. W. Co. is also owner of one-half of 56.71 second feet of water decreed to the Platte and Denver Canal and Milling Company as of October 7, 1864 for Power purposes. Conveyed to it September 1, 1910.

Water was first stored in Marston Lake in 1892 by the Citizens Water Company. The lake has been enlarged greatly since first acquired. Its storage rights are in adjudication, there having been no reservoir adjudication in that district since its acquisition.

Printed pages 15-19 contain a list of the water rights of the D. U. W. Co. and the S. P. C. & R. Co. regarding which I have testified. Admitted as detailed testimony of witness. Printed pages 20-21 contain copy of the official record of the precipitation at Denver and Lake Cheesman. (Admitted to be correct by Defendants.) Admitted as detailed testimony of witness. Exhibit V is a certified copy of map and statement of claim filed by the S. P. C. & R. Co. for the 60 inch pipe line. Offered and admitted.

Direct examination by Mr. Dorsey:

The waters which have come through the various rights acquired by the D. U. W. Co. and the S. P. C. & R. Co. as described have been used continuously since their acquisition in increasing quantities as the growth and development of the city demanded for domestic use and for irrigation of lawns and gardens, extinguishing of fires and general city purposes in the city of Denver and by the water company for the irrigation of its various farms and ranches. These uses have been continuous since the rights were acquired. Much of the water used for the city of Denver is used for manufacturing power and elevator purposes.

Cross-examination by Mr. Patterson:

In addition to acting as secretary of the D. U. W. Co. I also assisted our attorneys in legal matters. Am also secretary of the

Mountain Water Works Construction Company. (Objec-
248 tion by counsel as to examination concerning Mountain Water Works Construction Company overruled.) According to my understanding the Mountain Water Works Construction Company has not acted as holding company for either the D. U. W. Co. or the S. P. C. & R. Co. The Mountain Water Works Construction Company in 1894 became the owner of the D. U. W. Co. stock apportioned to the Citizens Water Company when the consolidation was effected. It received $1,250,000 of preferred stock and $4,000,000 common stock par value. At the same time there was issued $7,000,000 in bonds. The Citizens Water Company received its proportionate share of the bonds and the reorganization committee of the Denver Water Company and the Denver City Water Works Company its proportionate share. Bonds to the amount of $1,000,000 remained in the treasury to be used for additions of the plant. $2,500,000 of bonds went to the Citizens Water Company. $4,500,000 to the Reorganization Committee. The remaining million dollars of bonds was subsequently issued and used in new construction. The corporate life of the S. P. C. & R. Co. was extended subsequent to the expiration of its charter under the statute providing for one year of grace after the expiration of the corporation life of a company for renewal. The lease from The S. P. C. & R. Co. to the D. U. W. Co. is the basis of the right of the D. U. W. Co. to use the property of the S. P. C. & R. Co. but The D. U. W. Co. owns all of the capital stock of the S. P. C. & R. Co.

(Reading by Senator Patterson of provisions of the mortgage of the S. P. C. & R. Co.) I think after The D. U. W. Co. turns over to The S. P. C. & R. Co. its property in as good shape as received, except for the ordinary wear and tear, upon the expiration of the lease that it will have performed its obligation under the lease. The S. P. C. & R. Co. constructed the new pipe line to Marston Lake. No construction company was connected with The S. P. C. & R. Co. in connection with the building of Cheesman Dam or any of the pipe lines. The first money for the Cheesman construction was advanced by The Mountain Water Works Construction Company. With that exception it had nothing to do with the Construction work for The S. P. C. & R. Co.

The first water plant in Denver was located at 15th and Bassett Streets in 1872. In 1874 its capacity was 4,500,000 gallons daily. In 1878 this capacity was increased by the Denver Water Works and Irrigation Company constructing the West Denver Pump Station to 9,500,000 gallons daily and in 1882 by an addition to that plant to 14,500,000 gallons daily. In 1886 the Domestic Water Company,
a subsidiary of the two holding companies constructed the
249 Cherry Creek works. In the same year the Beaver Brook Water Company was organized to supply the town of Highlands and The Mountain Water Company to supply the town of Barnum, these companies were independent of the companies operating in Denver proper.

Up to that time the water supply was taken from the adjacent streams with no provision for storage. Appreciating the necessity

for an additional supply with reservoir storage, local stock holders discussed with Mrs. Archer who controlled the Denver Water Company a plan to go to the mountains for a water supply. Mrs. Archer refused to cooperate. Local stockholders then proposed to buy her stock or sell her theirs informing her that if they sold and proper provisions were not made for a water supply that they could carry out the plan to go to the mountains for an additional supply. As a result of this situation the Citizens Water Company was organized, constructed intake works and a pipe line 30 inches in diameter 23 miles long from Platte Canon to the north side of Denver from which the supply was distributed by gravity. Within 4 years it had constructed a second conduit 34 inches in diameter, 23 miles long, and installed the first artificial filtration plant west of the Mississippi river. Water for this conduit and filter plant was supplied by the rights purchased in the Platte Canon Ditch. The Citizens Water Company and the American Water Works Company of New Jersey were in competition until 1894. In April an agreement was reached between the parties for the purchase of the property by a new company to be organized. Rates for water service were not restored until after Oct. 1894. The Citizens Water Company during the competition supplied water free.

The American Water Works Company cut the rates, the Citizens Water Company met the cut, the American cut again and the Citizens offered water for nothing. I think water is supplied now for almost nothing. The old company cut rates first, it also supplied water free where consumers did not pay. Work was commenced on Cheesman Reservoir shortly after the organization of the S. P. C. & R. Co. in 1894. The first dam planned was a rock fill dam with a steel face in masonry. That dam was washed out in 1900 when it had been built to a height of about 50 feet. There was a small natural lake at the site of Marston Lake called Ford's Lake. In constructing Marston Lake the company took advantage of the contour of the ground, threw the earth work around and impounded the waters, excavating the material to form the dam or embankment. The D. U. W. Co. owns $888,000 of the bonds of the S. P. C. & R. Co. (Objection to Interrogation along this line overruled.)

250 Money was advanced by the D. U. W. Co. for construction work and the bonds were taken in payment. The company became the owner of these bonds after the mortgage was executed, of course. Work had been going on at Lake Cheesman before 1897 but probably not on the dam. Construction of dam was completed in 1904. The bonds were issued and mortgage given by the S. P. C. & R. Co. in 1903. Up to this time the D. U. W. Co. had been furnishing the money for all of this work. The D. U. W. Co. paid $150,000 for the capital stock of the S. P. C. & R. Co. (Objection overruled.) The mortgage of the S. P. C. & R. Co. was dated May 1, 1903 and the bonds June 1, 1903. I think the records of the Auditor's office would show the delivery of those bonds better than my records. The bonds were delivered to the D. U. W. Co. from time to time as advances were made. The D. U. W. Co. did not withdraw any bonds until 1905, they then withdrew a million dol-

lars which were sold at once. The sale was made by the D. U. W. Co. of the bonds turned over to it. I practically negotiated the sale of the first million dollars.

Bonds of the S. P. C. & R. Co. were sold to pay for the construction of the new 60 inch pipe line, which work was done by the D. U. W. Co. The West Denver lands, the title of which is in Evans and Hayden Trustees, are used in connection with the water power for the West Side Pumping Plant. They were conveyed direct to the trustees by Mr. Underwood, representing the Reorganization Committee. Title was placed in trust because it was thought that the lands might be disposed of to be used for purposes other than water works purposes, but it has been found impossible to do away with the West Denver works. Whether the mortgage of the D. U. W. Co. covers the stock of the Littleton Milling and Water Power Company and the S. P. C. & R. Co. is a legal question. I have forgotten how much land was acquired with the first rights purchased in the Platte Canon Ditch, 300 or 400 acres possibly. 1902 is the only year in which the Platte Canon Ditch has been shut off because of scarcity of water. There never has been any litigation concerning the claims of the company under the Platte Canon Ditch. Two men, named Hugins and Shellabarger have rights to irrigate 195 acres which are recognized by the company. We have used all of the water of that ditch in the non-irrigating season.

I don't believe any steps were necessary to change that from an irrigation to an all-year-round use except to use the water for the new purpose. The all year round use was initiated in 1889 or 1890. The original intake of the Platte Canon ditch is still in use for carrying water to the ranches and for part of the city supply. Most of the city supply comes through the conduits.

251 Application for a decree for a change of point of diversion of this ditch to the conduits is now pending in the district court of Douglas County. The case has been pending since 1904 or 1905, being known as cause No. 558. We claim the total appropriation of the Platte Cannon Ditch 56 second feet for use during the non-irrigating season and 52.86 for use during the irrigating season. During the non-irrigating season we use all of the first appropriation 4.70, anl during the irrigation season 1.56 second feet. The right to the full supply during the non-irrigation season was initiated by taking and using with the consent of the owners in 1889. The original appropriation for the first water plant has never been discontinued. It is now used through the Mississippi Street galleries. The only step taken or necessary to be taken to change the point of diversion was the physical act of taking the water at a new point of intake. The right to change was never called into question by court proceedings.

We claim an appropriation of 30 cubic feet for the Mississippi Street galleries through the same conduit that carries the original 2.50 second feet. The Mississippi Street galleries were first used, I think, in 1879. The proceedings for the adjudication of the domestic rights were instituted in Douglas County immediately after passage of the statute authorizing such proceedings. The Galleries

were constructed at Platte Canon in 1889. I think no filing was made for this water because the law did not permit of any. A statement of claim has been filed in the adjudication suit that is still pending.

Appropriation of 24.75 second feet for the thirty-four inch conduit and 38.8 second feet for the 40 inch conduit was made in the same manner by construction and taking of water. The law under which filings could be made for such purposes did not go into effect until 1903. Statement of claim was filed in the State Engineer's office March 8, 1912, for the 60 inch line. 120 second feet is the full capacity of that line. The list introduced covers all of the water rights owned, leased or used by the D. U. W. Co. in furnishing a water supply to Denver. It has no leases or contracts for water supply except from the S. P. C. & R. Co. Marston Lake was often filled from the Turkey Creek and Bear Creek rights. Court proceedings have not actually been started for the adjudication of the enlargement of the Harriman Ditch. The enlarged capacity has been used, whenever the water was available, ever since 1892. The enlargement was for both domestic and irrigation purposes.

The Archer Lake and Platte and Denver Ditch rights are for power purposes. The Platte and Denver Water is used
252 through the Archer Canal. None of it is used for domestic supply. Rights acquired by the Water company which were originally irrigation rights have been used in part for irrigation and in part for domestic supply. Since 1894 new rights have been initiated by the construction of two or three conduits and by the purchase of Harriman Ditch, Soda Lakes, and Bergen Ditch rights, evidenced except the Harriman Ditch enlargement, by stock in the Companies. They were acquired as a matter of precaution to add to the water supply. The company now irrigates no land under the Harriman Ditch. It disposed of the Harriman Ranch and retained the water supply representing one-fourth of the supply of the Harriman Ditch. The Harriman rights were converted into domestic or all-year-round-use, simply by using them through Marston Lake. The Harriman Lake never has been used for domestic supply but can be used through Marston Lake any time. Large extensions of the distribution system were made with the million dollars in the treasury of the D. U. W. Co. after its organization. Part of that money may have been used in construction of Lake Cheesman. The Mountain Reservoir (Strong) never was used. It was acquired by the Citizens Water Company for reservoir purposes. Much money was spent on it. The Water company recognizes the season in which water is needed for growing crops as the irrigation season.

There is a statute that requires an irrigation company to supply water from such a date in the spring to such a date in the fall.

Redirect examination by Mr. Dorsey:

The term consolidation used in respect to the formation of the D. U. W. Co. in 1894 applies to a property and not a corporate consolidation. The D. U. W. Co. purchased the properties of the Ameri-

can Water Works Company and the Citizens Water Company. The capital stock of the S. P. C. & R. Co. was acquired by the D. U. W. Co. June 10, 1899. Lands to which title is in Evans and Hayden trustees are expressly excepted by the mortgage of the D. U. W. Co. The lands appurtenant to the water power of the West Denver station constitute a majority of the property so held. The change of use from irrigation to all-year-round use of the Platte Canon Ditch right effective since 1889 never has been questioned by anybody. It has been known and recognized by all interested parties including the state engineers and water commissioners. Power water has not and could not be used through the pipes for consumers. The Platte Canon Ditch was shut off from the latter part of July to September
21, 1902, because there was not enough water in the river to
253 supply even the first appropriation from the river during that period.

I have been familiar and connected with water rights and water supplies in Colorado since 1875. 1902 was the driest year in the stream flow history of Colorado. All of the Harriman Ditch water is used for city supply. Harriman Lake in a sense supplements the city supply because certain contracts made by George W. Harriman to supply others with water from his rights have been shifted by us to Harriman Lake so they do not interfere with the Harriman Ditch rights.

Recross-examination by Mr. Nye:

The D. U. W. Co. in 1894 purchased part of its property from the Citizens Water Company and part from William A. Underwood who represented the Reorganization Committee. He had purchased the property of the American Water Works Company at Master's sale. This purchase included the rights and equities of the holders of securities of the Denver Water Company, The Denver City Water Works Company, and the American Water Works Company. And included the underlying mortgages of the Domestic Water Company, The Beaver Brook Water Company and the Denver City Water Company. There were two sales, one under the Denver Water Company mortgage the other under the Denver City Water Works Company mortgage, both purchases were by Underwood.

Witness W. P. MILLER recalled.

Direct examination by Mr. Hodges:

Exhibits BB and CC are certified copies of filings made by the S. P. C. & R. Co. in the office of the Register of the United States Land Office at Denver for right of way on the public domain for Lake Cheesman Reservoir. First filing was made in 1895 and under the law which gave the company five years to complete its work. Second filing was made in 1900 and proof made of litigations, etc., that delayed the completion of the work. Offered and admitted. Exhibit DD is a certified copy of the articles of incorporation of the Arnett Ditch Company. Offered and admitted. Exhibit EE is a

certified copy of the articles of incorporation of the Harriman Ditch Company and extension of its corporate life. Offered and admitted. Exhibit FF is a certified copy of the deed from the Arnett Ditch Company to the Harriman Ditch Company. Offered and admitted. Exhibit GG. are copies of the stock certificates of the Harriman Ditch Company owned by the D. U. W. Co. Offered and admitted.

Exhibit HH is a certified copy of the decree of the District
254 Court of Arapahoe County for Water appropriations in Water District No. 9. The decree was entered in 1884. Since the decree was entered there has been an enlargement of the Harriman Ditch. Offered and admitted. Exhibit II, is a certified copy of the statement of claim filed by the Harriman Ditch Company in the office of the State Engineer, Sept. 21, 1892, making an additional appropriation from Bear Creek for the Harriman Ditch and its stockholders to fill nineteen reservoirs, including Marston Lake. The claim being for the unappropriated waters flowing in Bear Creek in the irrigating and non-irrigating seasons. Offered and admitted. A copy of said statement of claim was also filed in the office of the Clerk and Recorder of Jefferson County. Immediately upon the filing of the claim, work was commenced to enlarge the ditch to a carrying capacity of 125 cubic feet per second. The work was executed by the Citizens Water Company for the Harriman Ditch Company. The Ditch has since carried the full appropriation whenever water was available. The water derived by the Water company under its interests in the ditch has been put into Marston Lake and used for city supply.

The water company owns the one-fourth interest in the Harriman Ditch which entitles it to one-fourth of the water supply at all times. It has a further interest under contracts with the Harriman Ditch Company entitling it to any surplus supply that may not be needed by the other users under the ditch. This is over and above its one-fourth interest.

Exhibits JJ, KK, LL, are copies of three contracts which have been in effect covering this water supply. JJ, and KK, were between the Harriman Ditch Company and the Citizens Water Company. LL, between the Harriman Ditch Company and the D. U. W. Co. The waters of the Harriman Ditch Company have been constantly used for irrigation purposes except the portion belonging to the D. U. W. Co. which has been used for city supply. This city supply began with the first contract between the Harriman Ditch Company and the Citizens Water Company in 1892. The records of the use of water through that source for city supply are in Exhibit C. at page 32. Exhibits JJ, KK, LL, offered and admitted.

Exhibit MM, is a copy of the certificate of incorporation of the Bergen Ditch Company offered and admitted. Am not familiar with the titles of the Bergen Ditch Company except with the appropriation decreed in Exhibit HH, numbered 18, priority No. 27. The ditch has since been enlarged. Water decreed to the Harriman Reservoir on page 25, of Exhibit HH is carried through the Harriman Ditch. Exhibit NN, is a copy of the certificate of incorporation

of the Soda Lakes Reservoir and Mineral Water Company.
255 Offered and admitted. Exhibit OO is a certified copy of the map and statement of claim filed by the Harriman Ditch Company in the office of the County Clerk of Jefferson County, Feb. 11, 1893., making an appropriation of water for the Soda Lakes Reservoir. Offered and admitted. Exhibit PP is a certified copy of the deed by the Harriman Ditch Company to the Soda Lakes Reservoir and Mineral Water Company, conveying the Soda Lakes Reservoir and claim for water under Exhibit OO. Offered and admitted. Water under said filing has been stored in said reservoir, then used for irrigation except the water owned by the D. U. W. Co. which has been run from Soda Lakes to Marston Lake through the Harriman Ditch. The D. U. W. Co. owns 110 out of 400 shares of the Soda Lakes stock. Soda lakes takes water from Bear Creek. Harriman Lake from Turkey Creek, The Bergen Ditch from Turkey Creek. Water decreed the Harriman Lake has been used continuously for irrigation. Harriman Lake has been enlarged since the decrees were entered in 1884. Obtains part of its water under the enlargement of Harriman Ditch. The D. U. W. Co. acquired Marston Lake from the Citizens Water Company, which acquired the original plot of ground from James Marston. Subsequently purchases were made from Bowles, Skelton and others of land sufficient to make it as large as it now it.

There is no specific decree for Marston Lake. Water was first stored there in 1892 or 1893. Since then it has always been used for city supply. The lake is many times larger now than when storage was first made. Construction work was completed on it in 1902. Exhibit QQ is a copy of the articles of incorporation of the Littleton Milling and Water Power Company and extension of its corporate life. Offered and admitted. Exhibit RR is a copy of the certificate of incorporation of the Denver City Water Works Company. Offered and admitted. Exhibit SS is a copy of certificates of incorporation of the Denver City Water Company and of the Denver City Irrigation and Water Company. Also articles of consolidation of the Denver City Water Company and Denver City Irrigation and Water Company, into the Denver Water Company, and an amendment thereto. Offered and admitted. Exhibit TT is a copy of certificate of incorporation of the Domestic Water Company. Offered and admitted. Exhibit UU is a copy of certificate of incorporation of the Mountain Water Company. Offered and admitted. Exhibit VV is a copy of the certificate of incorporation of Beaver Brook Water Company and an amendment thereto. Offered and admitted. Exhibit WW is a copy of certificate of incorporation of the American Water Works Com-
256 pany. Offered and admitted. Exhibit XX is copy of articles of incorporation of the Citizens Water Company, and renewal thereof. Offered and admitted.

Redirect examination by Mr. Dorsey:

I have personal knowledge regarding a few of the items of expenditure shown on Exhibit Z. The item of $10,500 for stock of

the Soda Lakes Reservoir and Mineral Water Company was in payment for stock in that company purchased by me for the D. U. W. Co. in 1910. Items of $12,500, $1090, $91, expended in 1910-11-12 were for the acquisition of a one-half interest in the Platte and Denver Ditch Company's Ditch known as the Mill Ditch. Items $1620. $252. in 1911 and '12 for Bergen Ditch Water rights, were in connection with the enlargement of the Bergen Ditch and Reservoir Company's property. Am familiar also with the sales of real estate shown on Exhibit Z resulting in separations from the plant as appraised in 1908 of property for which the company received $40,547.20 subject to deduction of $269.30 for expenses leaving the net amount received $40,277.90. The amount received for all of the real estate was something like $4,000 more than the appraisement.

All of the items sold for the appraised valuation or better, except two parcels that were condemned for city purposes. 750 acres of the Harriman Ranch were sold as dry land for $28,250. The water rights were retained and 130 acres of land surrounding Harriman Lake. All of the ranch lands of the company were acquired in order to obtain the water rights connected with them. The Platte Canon Ditch rights were obtained in connection with the Platte Valley ranches. The Strong or Mountain Reservoir Site, is entirely independent of the Strong Ranch. The company still owns the Platte Valley ranches and has retained them to preserve and continue the use of the water rights derived with them at the times when all of the water is not needed for city purposes. The water is taken from the ranches whenever it is all needed for city purposes, but in order to keep the full amount of these water rights constantly applied to a beneficial use it is necessary to maintain the ranches.

The company was able to dispose of the Harriman Ranch because it is able to use all of the water available from Bear Creek for domestic purposes, at all times. The conduits of the company pass through the Platte Valley ranches as indicated on Exhibit B. The company acquired the Littleton mill property in 1903, as a protection to both the summer and winter flow of the Platte Canon Ditch. The
257 right for the mill being earlier than the rights of the Platte Canon Ditch and could demand the water in times of shortage if owned by other parties. Ownership of that right also protects the company against claims against the Platte Canon rights by the Nevada Ditch which are earlier than some of the Platte Canon Ditch rights but later than the Rough and Ready rights. In order to keep this right alive it is necessary to operate the mill. The Platte and Denver Ditch right is valuable for the benefit of the Mississippi Street gallery rights in the same manner. The Strong Reservoir site was acquired before the discovery of Lake Cheesman. Considerable money was spent on it. There are 8436.10 acres in the Lake Cheesman Site. 7,636.10 acres were conveyed by the United States Government by special act of Congress. All of submerged acreage is included in that act. 800 acres were purchased from the State of Colorado. Prior to obtaining this 7,636.10 acres, the company had

filed on a reservoir site at this location. First filing made Oct. 8, 1894. Second filing April 12, 1900. Those filings covered 800 acres approximately.

The patent issued under the special act covered the land also included under those filings. 250 to 300 acres of this land was also covered by title obtained through the Olive and Estella Placer claims and an additional acreage through other placer claims, for which patent was obtained before the blanket patent covering all of the land was applied for. The company paid the United States $1.25 an acre for all of the land described in the patent notwithstanding the fact that it had other title and other rights to a large portion of it.

The land purchased from the State of Colorado was not covered by the United States patent. Exhibit ZZ, is a copy of the franchise from the city of Denver to the Denver City Water Company, dated Dec. 16, 1870. Offered and admitted. Exhibit A1 is a copy of the franchise from the city of Denver to the Denver City Water Company dated May 9, 1874, succeeding exhibit ZZ. Offered and admitted. Exhibit A2 is a copy of the franchise granted the Citizens Water Company by the City of Denver. Offered and admitted. Exhibit A3 is a copy of ordinance No. 44, 1890, a franchise granted the Denver Water Company by the City of Denver, April 10, 1890. Offered and admitted. Those are copies of all of the franchises that have existed between the city of Denver and the various water companies that have served it except that different companies had contracts with small municipalities originally independent and now a part of the City and County of Denver, which contracts were assumed by the City and County of Denver until their expiration. There is also the lease of the City of Denver to the Denver Union Water Company for the use of the water system in South
258 Denver. The franchises of the Citizens Water Company and the Denver Water Company ran concurrently.

The Citizens Water Company and the American Water Works Company successor of the Denver Water Company were in competition from 1891 until 1894. One result of the competition was large reductions in water rates and ultimately the furnishing of free water. Schedule A of water rates is the schedule that was attached to the franchise of the Denver Water Company. Competition ceased between the companies April 6, 1894, when an agreement was made for the purchase of the properties of the two companies by a new company to be formed.

The Denver Union Water Company acquired the property and franchises of the two companies in Oct. 1894. It chose to operate under Ordinance 44, series of 1890. It restored the rates of Schedule A, except the $10 per lot rate for lawn irrigation which was reduced to $5.50 per lot. Those rates remained in effect until the next year when a controversy arose over the provision of the ordinance that in April 1895 the rates should be reduced to the average of the rates of Cincinnati, St. Louis and Chicago. A number of rate schedules were proposed by the company, none of which were accepted by the City Council. After the then mayor had advised the people not to

pay the rates charged by the company and offered to furnish keys with which to turn on water if it was turned off to enforce payment the city brought suit against the company to require it to make the reduction contended for. Meanwhile ordinances were enacted providing penalties against officers and employes of the water company should they attempt to enforce collections under the then existing schedule. Enforcement of these ordinances was enjoined in a suit brought by the Continental Trust Company against the city of Denver and in the United States Court in St. Louis before Judge Thayer, that injunction was made permanent. The suit to require a reduction in rates was begun May 21, 1897. Nine months were consumed in the trial of the case which finally was decided by the Supreme Court of Colorado in 1907. The leaflet schedule under which the company is now operating was the schedule that was offered as a compromise in connection with this rate controversy. After the case was decided by the Supreme Court, the Leaflet Schedule was put into effect.

After the D. U. W. Co. came into possession of the property of the old companies litigation developed with Clarence H. Venner and others attacking the foreclosure proceedings which was carried through the courts for years. Some of the cases were in the Federal Courts, some in the State Courts. Some in the Courts of New Jersey. One case went to the Supreme Court of the United
259 States, and was finally decided in 1910. The water company was successful in all of this litigation. After the decision of the Supreme Court of the United States in 1910 other litigation on behalf of Venner was begun in 1912 and '13. The Venner litigation involved the title of the company to its property. The litigation with the city and others related to the question of rates and to pressure and purity of the water supply.

There was also litigation over the adjudication of water rights and in 1900 an injunction proceeding to restrain the city from issuing $4,700,000 bonds to build a competing plant. Also litigation with the Colorado and Southern R. R. and others arising from flood damage caused by the failure of the first Cheesman Dam which was washed out by a flood. Then came the appraisal of 1907 in which legal expenses were incurred and following that the Suit of the New York Trust Company against the City and County of Denver respecting Ordinance 44, of 1890.

Before I became connected with the D. U. W. Co. I was for many years connected with the Colorado Mortgage and Investment Company. (Objection to inquiry as to interest rates overruled. Exception.) From 1869 to 1875 the prevailing interest rate was 2 per cent per month, from 1875 to 1880 12 per cent per annum and on especially valuable security 10 per cent. From 1880 to 1885, 8 per cent, from 1885 to 1890, 8 per cent, from 1890 to 1895 some money was loaned at 7 per cent but no good loans at less than 8 per cent. From 1894 to recent years farm loans ran from 6 to 7 per cent and on approved security in the city 6 per cent as the minimum.

(On Motion of Mr. Nye, testimony of the witness Miller concern-

ing interest rates prevailing prior to the incorporation of the D. U. W. Co. in 1894 was stricken out as incompetent, irrelevant and immaterial, and not within the issues of this case. Exception.) The Olive and Estella placer claims contained 254.825 acres, the Canon Lode and Mill Site, 15.331 acres. The Watson Placer 86.327 acres. A total of a little over 356 acres. The Olive and Estella Placer claims had been filed upon and partially developed by others. The S. P. C. & R. Co. bought out the claimants. The S. P. C. & R. Co. caused the other claims to be filed upon to cover the dam site and spillway. The S. P. C. & R. Co. caused the necessary development work to be done so that it obtained patents to those claims for the purpose for which filings were made.

Exhibit A5 contains a list of lands acquired by the water company from Jan. 1, 1908 to Oct. 31, 1913. They are lands not included in the 1907 appraisal and now owned by the water
260 company. The consideration is not on the list but can be supplied. Exhibit A.5. Offered and admitted. Exhibit A.6 is a list of rights-of-way for conduits acquired from Jan. 1, 1908, to Oct. 31, 1913, not included in the 1907 appraisal. They are now owned by the water company. Exhibit A.6. Offered and admitted. The lands are listed under the number of the conduit or item of property with which they are connected. The costs of these lands is included in Exhibit Z.

Cross-examination by Mr. Nye:

Exhibits BB, and CC, will themselves show the date of filing. CC. was executed Oct. 8, 1894, approved by the Secretary of the Interior, Aug. 14, 1895. Exhibit BB was filed April 12, 1900, approved by the Secretary of the Interior, July 3, 1900. I was in error in my direct testimony as to the time of those filings. The Citizens Water Company was not a stockholder of the Harriman Ditch Company when the claim to enlargement was made in 1892. It was interested under the first contract with the Harriman Ditch Company, which was made about the same time. The Citizens Water Company enlarged the ditch, the increased capacity being made necessary by the enlargement claimed. The ditch has since carried its full capacity to Marston Lake and other reservoirs whenever water was available. An enlarged use for irrigation purposes was made from that time, more land being put under cultivation. The increased use by the stockholders, other than the water company was for irrigation. I don't know what portion of the enlarged capacity is necessary to carry the irrigation rights. The first few years after it bought the Harriman Ranch the water company attempted to farm it and use part of the water for the ranch, then finding it needed it all for city supply it gave up supplying water to the ranch. I don't know just how long it is since we ceased using any water for irrigation for the ranch. No portion of the right has been used for irrigation since the sale of the land. The Harriman Ranch was acquired by the D. U. W. Co. May 17, 1897. Marston Lake is located several miles from the Harriman Ranch. The Marston Lake site was originally acquired by the Citizens Water Company. I don't know what

the cost to the company of the site was. The books will show. Since my connection with the company several pieces of land have been purchased at prices of $100, $150, $175, an acre. It is my recollection that $150 an acre was paid for the land that was condemned. I can ascertain what the reservoir site cost.

The rights of Marston Lake are subject to decree and can be decreed. No petition has been filed for a decree. In conveying their properties to their successors the different predecessor com-
261 panies of the D. U. W. Co. generally executed more than one deed. Real estate being conveyed by instruments separate from rights of way, water rights, franchises, etc. The transfers were all made at the same time however. The Platte and Denver Ditch is not now used except to irrigate a little land near the headgates. We bought only the power right and transferred our half into Lake Archer. The headgate of the Platte and Denver Ditch is about two miles from the Archer Canal. We have not applied for a decree changing the point of diversion. The matter is open now in a suit pending in Douglas County. We acquired one-half of 56.71 second feet. We have made use of the water ever since we purchased it. The right was simply added to the existing power rights of Lake Archer which were increased to the extent of that purchase. Referring to the real estate separated from the plant since the former appraisal, Block 7 Weir's Addition was sold for $1,200. Plats, 2, 7, and 8 Block 38 East Capitol Hill, was condemned by the city, we were awarded $597.20. Lot 19, Block 33, Witter's First Add. also was condemned for street purposes, we were awarded $500. The Alameda Avenue Tank Site was sold for $10,000. 750 of the 880 acres of the Harriman Ranch was sold as dry land for $28,250.

The board of appraisers fixed the value of the Harriman Ranch 880 acres including the Harriman Reservoir and the works creating it, with surplus water for the ranch at $40,300. I was familiar with the Platte Canon ranches before their purchase by the water company. The Frank Archer ranch is in a higher state of cultivation now than before the purchase. The other three are not. The first priority of the Rough and Ready Mill Ditch for 37 second feet is dated Dec. 31, 1860. The second priority is dated Dec. 31, 1867. Only the first priority prior to the Platte Canon and Nevada Ditches, and is the one that is important in protecting the rights of the Water company. 840.224 acres for the Marston Lake reservoir site were purchased between Dec. 22, 1892 and Feb. 20, 1911 for a total direct consideration of $87,867.15. The dates of purchase, grantors, and purchase prices paid are as follows:

December 22, 1892, purchased of H. W. Lake, 88.03 acres, $11,003.75; on the same date purchased of J. W. Bowles, 106.67 acres, $13,333.75; March 8, 1894, purchased of Lucy G. Elliott, 28.59 acres, $4288.50; August 10, 1894, purchased of F. S. Meston, 320 acres, $27,200; purchased on March 28, 1894, condemnation suit, Trout Lakes, and so forth, Company, and Boyd Skelton, 120.90 acres, $18,175; and on the same date, I think, purchased of J. W. Bowles, 8.28 acres, $1035; and another tract, of the same party, 2.45

acres, $306.25; another tract of the same party, 42.11 acres, $5263.75. Another tract from the same party, 2.14 acres, $267.50. Au-
262 gust 14, 1898, purchased of Lucy G. Elliott, 28.44 acres, $1457.50; January 31, 1900, purchased of Lucy G. Elliott, 6.57 acres, $328.50; February 26, 1901, purchased of J. A. Osner, .215 acres, $64.50; about the same time, although the date is not here, perhaps the same day, purchased of J. W. Bowles, 16.84 acres for $850; and another tract from the same party, 67.28 acres, $4,036.80; February 20, 1911, purchased of J. A. Osner, 1.709 acres, $256.35, making a total of 840.224 acres, for $87,867.15.

All the purchases prior to Oct. 1894 were made by the Citizens Water Company, and conveyed to the D. U. W. Co. by the deed in this case as an exhibit. There was an advantage to the D. U. W. Co. in transferring the point of diversion of the Mullen Ditch from a point above the Mississippi Street galleries to a point below them as protection to the gallery rights. Work ceased on the Strong reservoir site at the time the Cheesman site was discovered. The use of the Strong site has been postponed until additional reservoir capacity is needed. It would have to be supplied by the construction of a long canal or pipe line from the Platte River. The diversion would have to be made about at the junction of the North and South forks. I don't remember the price paid for the state lands purchased for Lake Cheesman.

There were ten original locaters of the Olive and Estella Placer claim. I think it cost us about $15,000. to acquire the interest of the claimants, then we did the annual assessment for patent work, and were in litigation with B. P. M. Kimball over a 3/10 interest in the claim. Finally we bought him out and got the title. This was all done before we applied to Congress for the blanket patent. I will produce all of the information that I can concerning the original cost of Lake Cheesman Land. Parts of the lands were acquired by the Mountain Water Works Construction Company and I don't know whether we have those early books.

When the D. U. W. Co. was organized it acquired the franchises of the Citizens Water Company and the Denver Water Company. It chose to operate under the franchise of the Denver Water Company. The Citizens franchise was involved in litigation.

The Venner litigation involved the D. U. W. Co. directly, attacking of the property which it acquired except that acquired from the Citizens Water Company. The leaflet schedule originated in 1895. It was not in effect between 1898 and 1907, when a schedule provided by court decree was in effect. The leaflet schedule was in effect during the trial of that case, and suspended upon the entry of the decree of the District Court. I don't know whether all of the expense of litigation has been charged to operation or not,
263 that is not in my department. An injunction was issued by the Federal court in 1900 on complaint of Fanny Josephine Grant restraining the issue of $4,700,000 of bonds by the city, for the construction of a competing water plant. The case was not appealed and the city destroyed the bonds. The lands held by Evans and Hayden trustees include the lands in Lake Archer

but not all of the lands shown on Exhibit A. 4. They are listed by specific description in Exhibit C. The lands are now subject to the mortgage. They were put in the trust to enable us if we saw fit to sell the lands to reduce the mortgage indebtedness.

Cross-examination by Mr. Patterson:

We do not claim that we can divert the water of the Rough and Ready Ditch for domestic or city purpose. It serves to protect us against the rights of the Nevada Ditch that are prior to the Platte Canon Ditch. The Platte Canon Ditch rights are part of our domestic rights. The Denver City Irrigation and Water Company constructed Lake Archer. It was originally built to furnish both power and water. None of the water is now used for domestic purposes. Water for domestic purposes is obtained from the Mississippi Street galleries. The water from the Mississippi Street galleries does not run into Lake Archer. It never did.

The auditor's office is working on the cost of the purchases in connection with Lake Cheesman it will be several days before it can be gotten out. The water rights of the company which have been purchased as distinct from those obtained by filing are the Platte Canon Ditch rights, Soda Lakes rights, Harriman Ditch rights, Bergen Ditch rights, the Rough and Ready Ditch rights and the Platte and Denver Ditch rights. The Platte Canon rights were bought in connection with the William and Phebe Strong and the Becky and Frank Archer Ranches, four distinct holdings. The Platte Canon reservoir site was bought from Abba T. Titcomb, by the S. P. C. & R. Co.

The land cost from $100 to $200 per acre, I have forgotten the exact price. I do not know what the construction of the reservoir cost. Our books will show. We purchased a water right of one cubic foot per second in the High line ditch with that land. The stock in the Harriman Ditch was bought with the Harriman Ranch for which we paid in the neighborhood of $50,000. We paid something like $17,000 for the Rough and Ready right. The water company as a consideration for the surplus water of the Harriman Ditch enlarged the ditch and maintains and operates it. I don't know how much the enlargement cost. I don't know anything about the item of discount on bonds in Exhibit Z.

264

The prevailing rates of interest from 1895 to 1900 were 6 and 7 per cent, I have heard that some insurance companies made some loans on especially good security at 5 per cent but that was not the prevailing rate. I don't know of any loans made here at 5 per cent within the past two years. The lands, the title of which was in Evans and Hayden trustees, were subject to sale if it was determined by the water company that they could be spared and sold.

The lands covered by Lake Archer are part of the trust. Some other scattering lands and lots were also in the trust. (Descriptions of the lands included in the trust.) Argument over attempt of Senator Patterson to cross examine witness concerning right of way testimony given by witness Abner T. Young. Block 1, East Denver was part of the land under the original trust. I don't remember whether

we have sold the right of way extending from the West Denver Station to the old 15th Street pumping station. I don't remember any land being sold to the Denver North Western and Pacific Railroad except that block 1 East Denver. I do not know whether there is a plat available showing the property owned by the D. U. W. Co. immediately after its incorporation.

Redirect examination by Mr. Dorsey:

The amount realized from the sale of 750 out of 800 acres of the Harriman Ranch was $28,250. The valuation put upon the entire 880 acres as dry land including improvements, by McNeal and Sanborn was $23,478. The total value which the appraisers in 1908 placed upon the ranch with rights to surplus water and including the Harriman Reservoir complete was $40,300. So that there remains out of that appraisal to cover the water rights the 130 acres of land and the Harriman reservoir complete just about $12,000. The amounts testified to as having been paid for the Marston Lake lands were simply the purchase price or condemnation price paid directly to the land owner and they include nothing for the expense of collecting the land, legal, expenses, commissions, or anything of that sort, nor do they include taxes, or other carrying charges prior to the time when the lake went into service. Most of the purchases were made in 1894. The lands have increased in value very much since that time. The same is true as to the testimony regarding the lands for Lake Cheesman.

The Mountain Water Works Construction Company was not the construction company for the S. P. C. & R. Co. They were simply the owners of the site, and paid out some of their money for the acquisition of the site before the D. U. W. Co. purchased the stock of the S. P. C. & R. Co. The Mountain Water Works Con-
265 struction company never did any actual construction work for the S. P. C. & R. Co. It opened the portal of the tunnel at Lake Cheesman and built a small power ditch from Goose Creek to the site of the dam that was afterward abandoned.

Aside from that they simply put up the money to acquire the lands and made the surveys. The D. U. W. Co. purchased the stock of the S. P. C. & R. Co. from the Mountain Water Works Construction Company June 10 1899. The purchase price was $150,000. Up to that time the Mountain Water Works Construction Company had simply acquired the land and cleared some of the timber off the reservoir site. The cost to the D. U. W. Co. of acquiring these lands in the condition they were in was $150,000.

At the time of that purchase the S. P. C. & R. Co. had its filing on the Lake Cheesman site, had title to several mining claims and 640 acres of land purchased from the state. It had done practically no construction work. Its possessions around Platte Canon were acquired some years afterwards. After the purchase of this stock by the D. U. W. Co. the S. P. C. & R. Co. acquired at Lake Cheesman the additional 160 acres of state land and all of the land it acquired under the special act of congress. Construction work was completed at Lake Cheesman in 1904. The investment of $150,000

was practically idle capital from 1899 until 1904. The franchise of the Citizens Water Company was granted on the express condition that it should not sell out its plant, rights or privileges to or consolidate with or pool rates with any other water company furnishing water in the City of Denver. That was the principal reason why the Denver Union Water Company did not adopt that franchise. One of the reasons for the value to the company of ownership of the Rough and Ready Ditch arises from the provisions of the law under which the use of the Platte Canon Ditch was changed from irrigation use to an all-year-round use. The law requires that such change must be without damage to anyone. The Rough and Ready ditch being prior in time to the Platte Canon Ditch could claim such damage, if controlled by other owners. It would have been impossible for the Platte Canon Ditch to have perfected its right to the use of water during all of the non-irrigating season without that control of the Rough and Ready Ditch.

Recross-examination by Mr. Nye:

Marston Lake was in service and being used before it was completed to its present capacity. Use began in 1894 or 1895.
266 A little water was used from Lake Cheesman in 1903-04 before it was completed. We did not use any water from Lake Cheesman in 1902. There was a little stored there but we purchased emergency supply elsewhere wherever we could, holding that for a final reserve. The Citizens Water Company franchise was forfeited by the act of selling the plant to the D. U. W. Co. The Littleton Mill is frequently shut down in winter when all of the water in the river is needed to supply the Platte Canon Ditch demands for city purposes.

Witness W. P. MILLER Recalled.

Recross-examination by Mr. Nye:

93 acres of land purchased for the Platte Canon Reservoir cost $8,316, including a water right of 1 second foot in the High Line Canal. The purchase price of the Harriman Ranch was $34,808.50. The contract price was $40,000, but the company was allowed a credit for work to be done on Harriman Lake. Which work was carried out so that in effect the purchase price was $40,000. That included land and water rights. Objection by Mr. Dorsey overruled. Exception. Defendants' Exhibit 18 shows the dates of withdrawal and the amounts of the bonds of the S. P. C. & R. Co. withdrawn by the D. U. W. Co. from time to time.

Redirect examination by Mr. Dorsey:

85.25 acres of the Titcomb land was purchased Jan. 5, 1903. 7.7 acres were purchased before that. The Harriman Ranch was purchased May 17, 1897. Immediately after the purchase of the ranch we spent thousands of dollars on it putting it in shape. It was badly run down.

Recross-examination by Mr. Nye:

7,736.10 acres of Lake Cheesman land were purchased from the Government at $1.25 per acre. 800 acres were purchased from the State of Colorado for $3360. 160 acres at $5 an acre and 640 acres at $4. per acre. Our records do not show the purchase price of the placer claims. They were purchased by Mr. Cheesman who took in his own name and later transferred them to the company. There were a number of other mining claims in the Lake Cheesman site which we did not purchase but contested successfully after extensive litigation.

Redirect examination by Mr. Dorsey:

There were 20 or 30 of these filings and claims staked out on which we had to prove abandonment or contest. We also had
267 to buy out Dr. Crane who had a homestead claim covering the dam site. In the end we were forced to contest his claim.

Witness WILLIAM T. BARNES.

Direct examination by Mr. Dorsey:

I reside in Chicago, Illinois. Am a civil engineer. I have been engaged in that work 21 years, mainly in the water works field. During the past three years considerable of my time has been devoted to the preparation of inventories of water works properties for the purpose of valuation. Received my training at the Massachusetts Institute of Technology. Became connected with the property of the D. U. W. Co. October 1913 to prepare an inventory of same. Am member of the firm of Metcalf & Eddy. In preparing inventory worked directly under supervision of Mr. Metcalf with whom I have been associated since 1894, and have assisted in many of his appraisals. In some cases in the field work and in others in the office. The inventory was an independent inventory prepared by Mr. Metcalf and his assistants, who used the engineering force of the D. U. W. Co. about six men, which we increased to about 20 who were directly under my charge but the work was supervised generally by Mr. Metcalf and Mr. Anderson. We brought to Denver for the purpose, two men, who had been engaged in similar work elsewhere. Pages 1 to 61 of the inventory contain matters of general information prepared directly under the direction of Mr. Metcalf with which I had no connection except to assemble and compile. At page 13 appears a comparison between our figures as to the distribution pipe system and the figures of the Public Utilities Engineers to show the extent to which the two inventories were in accord. The difference is practically one-third of one mile. The two inventories are substantially in accord as to all elements of the physical property. Description of tables at pages 41 to 43 giving detailed information concerning the various conduits worked up from original field books and profiles of construction and supported by photographs showing conditions under which construction work

was carried on, difficulties encountered, etc. In addition to these records Messrs. Metcalf, Anderson, myself and such assistants as were necessary made frequent inspections of the entire property to obtain such additional information as was required. At many points excavations were made to expose pipe lines to joint inspection by us and engineers of the Utilities Commission for the purpose of indicating their condition.

268 Pages 65-97 of Exhibit C. are forms prepared for summarizing the inventory and the various items of property. Class A. pertaining to lands, B to water rights, T to furniture, materials, and personal property and the other classifications to the various other items of physical structure. Pages 109-395 inclusive contain detailed statement of the value and extent of individual items involved in the structures of the plant distributed according to the operating divisions of the company. Pages 399 to 815 inclusive contain more minute detailed information of the quantities of material, fittings, etc., of the classes of property for which valuations are set forth in pages 109 to 397. Interspersed between pages 111 and 395 appear maps, drawings, reproductions of photographs, etc., to show more explicity the situation as to the works. They are accurate reproductions of drawings, maps, and photographs on file in the company's engineering department made at the time of the construction of the works.

Cross-examination by Mr. Nye:

Every effort was made to have this inventory just as accurate as it is possible to make it. Many of the matters contained in Exhibit C. are the result of detailed field work under my direction. As to other matters we had to rely upon the company records. Columns 8 and 9 of page 41 give the slope per thousand feet and per mile of the hydraulic grade lines of the conduits, taking into consideration all elements that bear on the carrying capacity of the pipe. Photographs, illustrations, maps, etc., are typical selections from the records in the company office made by Messrs. Metcalf, Anderson, and myself. Those relating to river, railway, and street railway crossings were prepared specially for exhibit C. This is also true as to plates showing population curve and bacterial and chemical charts and as to a few photographs taken by Messrs. Anderson and Metcalf. Quantities of concrete, steel reinforcing, and such material as could not be inspected were taken from the estimates of the resident engineer. Quantities of structural steel were taken from the plans from which the structure was built. As far as we could we made personal inspection of all visible structures to check them with the plans.

Redirect examination by Mr. Dorsey:

Pages 13, 37, 38, 41 and 44, 62-97, 98-100, 111 to 395, and those portions embraced in pages 429 to 495 testified to by witness Barnes offered in evidence. Pages 105 and 106 containing "General Water Works statistics" were prepared either by me or under my personal

direction from census reports and such other records as were
269 necessary and available for the preparation of such information. For the past 20 years until recently my experience has been mostly on construction work. Should say I have been personally responsible for about $3,000,000 worth of work. From my experience I am of the opinion that the records, plans, etc., upon which this inventory is based are regular, well balanced construction records.

Objection overruled. Exception. Motion to strike overruled. In addition to the inspection of the records we also inspected in every instance possible the structure itself.

Witness WILLIAM T. BARNES Recalled.

Recross-examination by Mr. Nye:

Admission by Mr. Nye of the matters covered by the printed pages of exhibit C, testified to by the witness Barnes as the testimony that he would give concerning the specific items if especially interrogated as to each item subject to the general objection that the entire matter is incompetent, immaterial and irrelevant. Particularly specific objection to data comparing with report of the Public Utilities engineers. Overruled. Cost items on the weirs at Lake Cheesman taken from notes of field engineers because construction was different from plans. Cost items as to preliminary dam expense at page 121 taken from the auditor's record of that work. I do not undertake to answer for the accuracy of records of original construction except that from my experience as an engineer they appear to be well balanced and consistent.

Information as to the quantities involved in the construction of Marston Lake was taken from original records together with such field examination as was necessary to obtain complete information. Our results were in substantial accord with the results obtained by the engineers' committee who 5 or 6 years previously made a similar inventory. Information as to the puddled trench was obtained from plans and from a conversation with C. P. Allen, member of the Board of Engineers of the Public Utilities Commission who was in charge of that work for the company.

We did not consider the fact that the Littleton Flour mill and property was the property of another corporation. Objection to inclusion of this property listed in Class J, overruled. Items of pavement over mains represent the condition now existing without regard to condition when pipe was laid. Items appearing on page
371 concerning river crossings, etc., are based upon construc-
270 tion history and a very detailed survey of each crossing by a member of my staff so that the appraiser might have the most intimate knowledge possible of each crossing.

Redirect examination by Mr. Dorsey:

Many of the structures being underground it is impossible to inventory quantities and numbers by actual count, so we had to rely upon the best information available.

Witness CLARENCE GOLDSMITH.

Direct examination by Mr. Dorsey:

I am a hydraulic engineer, received my education at the Massachusetts Institute of Technology, graduated in 1898. Reside in Boston, Mass. From 1898 to 1905 was superintendent of water works at North Andover, Mass. From 1905 to Aug. 1907 Supt. of Public Works North Andover. August 1907 to Sept. 1911 was employed by the National Board of Fire Underwriters as hydraulic engineer. Since then, except for 11 weeks have been employed by the City of Boston in charge of the design and construction of a new high pressure fire system. National Board of Fire Underwriters is representative of 125 or 130 insurance companies, foreign and domestic, doing business in the United States. My duties were to inspect water systems to determine their ability to furnish fire protection. Made some 40 such inspections in the larger cities in the country including Denver.

Inspected Denver during a period of about 3 months, in Sept. Oct. and Nov. of 1910, examining every portion of the works. Pressure and flow tests were taken on different parts of the system and valves and hydrants were operated to determine their state of repair. The D. U. W. Co. did not indicate where such tests were to be made nor assist us in the making of the tests. The inspection in Denver was made in exactly the same manner as in other cities.

The conclusion arrived at after the inspection in Denver was that the system was adequate and reliable. The following are the cities in which I have made inspections similar to that made in Denver: Altoona, Pennsylvania; Atlanta, Georgia; Binghamton, New York; Boston, Massachusetts; Brockton, Massachusetts; Buffalo, New York; Butte, Montana; Camden, New Jersey; Clarksburg, West Virginia; Colorado Springs, Colorado; Columbus, Ohio; Day-
271 ton, Ohio; Detroit, Michigan; Fall River, Massachusetts; Great Falls, Montana; Helena, Montana; Lawrence, Massachusetts; Lincoln, Nebraska; Lowell, Massachusetts; Los Angeles, California; Lynn, Massachusetts; Missoula, Montana; New Bedford, Massachusetts; Norwich, Connecticut; Omaha, Nebraska; Ogden, Utah; Portland, Maine; Partial; Philadelphia, Pennsylvania; Pittsburg, Pennsylvania; Reading, Pennsylvania; St. Joe, Missouri; San Francisco, California; Seattle, Washington; South Omaha, Nebraska; Spokane, Washington; Salt Lake City, Utah; Tacoma, Washington; Toledo, Ohio; Wilmington, North Carolina; Worcester, Massachusetts; New Haven, Connecticut; Partial; making a total of forty-one. Comparing the reliability and adequacy of the plant in Denver with the plants in the other 40 cities it is my opinion that the Denver plant is equaled by only one of the others and that it excels all except that one. At pages 13, 38 and on plate 7A in exhibit C, occur accurate reproductions of parts of my report on the Denver works made in 1910. Plate 7-*a* is a map showing the pressure and quantities of water obtained in tests in the congested value district. Plate 7-*b* is a photographic copy of a tracing made by me of the entire distribution system of the D. U. W. Co. show-

ing pressures and quantities obtained in tests over the entire system. Quantity of water available in a water supply system is vastly more important than pressure in putting out fires.

There have been many important additions to and improvements in the Denver system since the inspection in 1910. Exhibit W. is a map showing the condition of the distribution system at the time of the inspection in 1910 with the additions to the system since 1910 added in yellow coloring and with the mains owned by the City of Denver identified in green. These additions were not put on the map by me personally but I checked them from the records of the company. The additions have had the effect of strengthening the system and increasing its capacity to deliver water. Have visited and examined the system three times since my inspection in 1910, have kept in touch with it from a fire protection viewpoint.

Through the construction of the 60 inch conduit it is possible to keep Marston lake constantly full and it is of great daily advantage to have such a supply of water in such proximity to the city.

Pages 45 to 48 of Exhibit C. contain quotations from the National Board of Fire Underwriters' report except as to the pressures there stated which are taken from a map prepared by me but which does not accompany the report. Such pressure records were
272 taken at 441 points on the system. The table on page 48 indicates the result of fire flow tests taken. The reference in the report to the outlying districts where pressures are not well maintained, refer to such sections as are indicated on Exhibit A. by the names Barnum, Argo, Globeville, Montclair, and certain portions of South Denver. Generally sparsely built residence districts. The report states the use of fire engines is necessary in all sections. To date 253 cities have been inspected by the National Board. There is nothing unusual in the fact that fire engines are necessary for the extinguishment of fire in Denver. In making our inspections we ascertain that the quantities of water necessary for fire protection are available over and above the maximum demand for water for domestic purposes. We ascertained that in Denver water is available under this condition commensurate with the risks involved.

In the congested value district Denver has a distinct advantage in a doubly assured supply because of the interconnection between the Capital Hill Gravity service and the North Denver Gravity service. The report states that the carrying capacity of the supply mains entering Globeville, Berkeley, and the Capital Hill High service are insufficient to meet the demands of maximum domestic consumption. The system in Globeville belongs to the city of Denver. Berkeley is the territory in the extreme northwest portion of the city shown upon exhibit A. Part of the mains in which belong to the city of Denver. Since 1910 however, mains have been laid by the D. U. W. Co. which materially strengthen the supply available in that district. The reference to South Denver was particularly to the southerly portion of that territory. At the time of the inspection nearly the entire

distribution system belonged to the City of Denver. Since the inspection the D. U. W. Co. has laid several large mains into that district that materially increase the quantity available. The territory referred to as the Capital Hill High Service relates to the portion lying east of Colorado Blvd. but more particularly to the section designated as Montclair. The booster pumping station is located on the main leading to Montclair. The reference to poor gridiron and much 4 inch pipe in outlying sections refers particularly to the sections shown on exhibit A. as Barnum, Colfax, part of Berkeley, Globeville, part of Elyria, and part of South Denver.

The new construction since the inspection has been materially beneficial, particularly, in Berkeley and South Denver. The other areas are generally sparsely settled. I have had to do with the installation and operation of engines, boilers, and pumping machinery for 20 years, in 1893 was connected with the engineering corps of the World's Columbian Exposition of Chicago as
273 chief observer of performance of machinery including engines and boilers. In 1895 was in charge as engineer, of installing boiler plants at the Cotton States International Exposition at Atlanta, Georgia. Was chief engineer in charge of the operation and in the salvage of the plant. I held engineer's license in Georgia and have held a first class engineer's license in Massachusetts. There was a previous inspection in Denver by the National Board in 1906. The board aims to inspect cities about every four or five years, except some that are growing slowly. Recommendations contained in that report have been complied with in part but not fully. Fireproof pumping stations have not been installed. That requirement however, is no longer made by the National Board. The recommendation to adopt meters to reduce consumption has not been complied with. 4 inch pipe has not been replaced. Most of it belongs to the City. Additional valves have been installed but there are still many lengths of mains which can be advantageously subdivided.

The average length of main required to be cut out in case of repairs in the congested value district is 542 feet. In representative residential districts the average is 860 feet. The standard of perfection adopted by the National Board and with which comparison is made provides for a maximum of 500 feet in congested value districts and a maximum of 1,000 feet in residential districts. In the congested value district the Denver system is very near the required standard and in the residential districts averages better than the required standard. Recent additions to the system have been along the best engineering lines. Many have complied with the recommendations of the National Board and others, notably the new conduit, are in addition to the recommendations of the National Board. 33 fire flow tests were taken in which 158 hydrants were opened, from four to seven simultaneously in the individual tests, depending upon structural conditions and strength of system. These were independent of the 441 pressure tests made. The locations for the tests were made by me without suggestion from the water company.

I had access to the engineering data of the company. I found that the quantities required for the protection of the congested value district were available about each block in the district and the quantities required for other sections were generally available. The system of parallel mains in the congested value district is a distinct advantage. The system is adequate and reliable in all particulars and sufficient for the purposes for which it is required. The 1910 report stated that the six wood stave gravity conduits were in good condition, well installed, and not subject to damage by flood.

274 I have visited the points where two conduits were recently damaged by flood. I have investigated the cause of that damage and find that it was due to a height of water which greatly exceeded any flood on the water shed prior to this time. My opinion expressed in 1910 was based upon the fact that the high water which had occurred up to that time would not have caused that damage. It appears that the river has left its bed and created a new channel for itself. In my opinion the damage was not due to defect in design or construction. The reports of field engineers of the National Board are reviewed by a corps of office engineers for approval or disapproval before the reports are issued. I am a member of the American Society of Mechanical Engineers, the American Society of Civil Engineers and the American Institute of Electrical Engineers.

Cross-examination by Mr. Nye:

The office of the National Board of Fire Underwriters is in New York City. I did not inspect Denver in 1906. The 1910 inspection began early in September. I went to the office of the company when I arrived in Denver and met Mr. Skouland, who was instructed to give me such information as I desired. In different parts of the inspection I was accompanied by Mr. Skouland, Mr. Thomas or Mr. Sweeney. I visited the main pumping stations and other parts of the system unaccompanied by anybody. The hydrant tests were laid out by me and run under my direction. I had four men in my own party and as nine men were necessary for the work the remaining five were borrowed from the Rocky Mountain Inspection Bureau. Mr. Skouland and Mr. Sweeney were present at these tests representing the company. These tests were independent of the pressure tests, totaling 441 over the entire system. The pressure tests were made from 1,200 to 1,500 feet apart over the entire system from the highest to the lowest points in order to determine the maximum and minimum pressure as well as the average. I determined at the time of the inspection that the six conduits were adequate to furnish the required supply to the city. The capacity of the 30 inch line was calculated as 8,000,000 gallons, the 34 inch line, 13,000,000 gallons, the 40 inch line 23,000,000 gallons, the 48 inch line, 25,000,000 gallons, the Cherry Creek line 5,000,000 gallons, the Mississippi Street line 14,000,000 gallons. That makes a total of 88,000,000 gallons.

The capacity of the two lines affected by the flood damage was 22,000,000 gallons, reducing the total supply capacity to 66,000,-

000 gallons. The serious condition caused by the diminution of supply was due to the fact that the maximum rate of con-
275 sumption has increased since 1910 and that the 40 inch line which lies in close proximity to the river was not being operated to maximum capacity for fear of damage to it. With the conduits out of service sufficient water is being furnished the city to meet any usual demand. It seemed to me in 1910 that ample precaution was taken against any damage that could occur. In fact, I stated in the report "The structural features of the supply works are well designed, permanently built and extraordinary precautions have been taken to avoid interruption in the supply by the installation of six conduit lines, well constructed and of ample capacity." If such an enormous consumption of water as is developed by Denver is necessary the accident has proved that the lines are not adequate with two out of service to furnish these large amounts. But these large amounts are considered wholly unnecessary. The consumption in Denver, however, has not been regulated by the installation of meters. If the consumption had been reduced according to the recommendations of the National Board the plant would have been able to deliver sufficient water with two conduits out.

I do not know that the Ashland Avenue Pumping Station was partly out of commission. The pumps were in operation when I was there Sunday afternoon at 5 o'clock. Salt Lake, Spokane, Ogden, Missoula, Helena, and Colorado Springs, of the cities that I have inspected use water for irrigation like Denver, none of them are metered. Investigation to determine the effect of the irrigation draft on the Denver System was made indirectly in 1910 by examination of pressure records for the previous year, though the use of water for irrigation had practically ceased at the time of the inspection. I took into consideration the effect upon the system of this greater draft in making my report. In connection with pressures taken at the time of the inspection at the 400 and odd points and the quantities discharged at the fire flow tests it is perfectly easy from the consideration I gave the matter to determine the effect that that consumption would have. I believe that the examination that I made for the purpose of this determination was sufficient. I have heard and known of failures of water supply in other cities similar to the failure that occurred in Denver due to these breaks. Altoona, Pa., Clarksburg, W. Va., Dayton, Ohio, Lawrance, Mass., Norwich, Conn., Omaha, Neb., Philadelphia, Pa., San Francisco, Cal., Seattle, Wash., Worcester, Mass., that is all that I can recall at the present time. Five of those were due to breaks or unforeseen accident and four to lack of supply. One was the flood in Dayton, another the earthquake in San Francisco. The precautions
276 taken in Denver were much better to avert accident than it has been my fortune to observe on other inspections. That these precautions were taken did not indicate any extraordinary necessity therefor. If they had not been taken, we would have recommended them. They were simply in accord with the general policy in the operation of the works, doing everything in as good

a manner as possible. The breaks occurred because the water rose over the pipes. I could not state whether the rise in the river was such as would have made it possible to have prevented the damage by protective construction.

It would have been good judgment to have taken preventive measures if one had known of the rise in time to prevent it. I cannot say whether those measures could have been taken without knowing how fast the river came up. (Objections to all preventive measure testimony overruled. Exceptions.) It is my opinion that the water pressure over the Mississippi Street line caused the break. The staves were in very good condition considering their age. I would not express an opinion as to the cause of the break near Platte Canon. It is my opinion that the break on the Mississippi Street line was not due to age. It is possible that the water came up so rapidly that it was adsolutely impossible to take precautions before the damage was done. I know nothing of the river stages except the maximum stage when it got over the pipe. (Objection to further interrogation on this line sustained.) I examined bands taken from the break they appeared to be in good state of preservation. It would not be my judgment that they should have been renewed, though I would not use them over again. Eliminating the question of the breaks the West Denver Station is not vital to the system in normal operation. The higher pressure figure and the lower pressure figure occurring beside hydrants on Plate 7-a show the pressures on the hydrant prior to opening and during the time they were open while the test was being taken. In making these tests we do not open as many hydrants as would be opened by the fire department in drawing a similar quantity of water, so a greater velocity is produced in the mains within the group than would be produced in the ordinary operation of the fire department delivering those quantities.

Check, pressure tests on hydrants attached to the main arteries feeding the group show a less drop in pressure than hydrants attached to the distributing mains within the group. Hydrants showing the lower pressures being on smaller mains. There are not enough hydrants in the congested value district. About 180 additional hydrants should be installed on the mains paralleling those to which the present hydrants are attached. The system has been
277 improved in other ways than by the installation of distribution pipes. The Pump Station in University Park has been enlarged increasing the supply of water there. The construction of the 48 inch line from Platte Canon to Marston Lake increases the quantity of water available to the city in case of fire by allowing an increased head on the mains through by-passing the filter plant, so that in emergency a large quantity of unfiltered water is available in the event of conflagration.

It also increases the supply of filtered water through permitting the constant operation of the Marston Lake filters up to capacity, which could not be done during a cycle of dry years while they were dependent entirely upon Bear creek and Turkey creek. Our reports purport to state the facts and necessarily in their presenta-

tion much more weight is given to matters of criticism than to matters of merit. Matters of merit are already satisfactory and the purpose is to get deficiencies corrected. We emphasize the things we criti-ze.

I have no recollection of what the connections recommended in the report of 1906 were that I stated in the report of 1910 had not been made.

In 1910 there still remained many lengths of mains which could be advantageously subdivided by valves. Up to 1910 no employes were detailed to attend fires, thus disregarding recommendation No. 15 of 1906. The number of hydrants is still insufficient. Some 180 hydrants are needed in the congested value district. Recommendation No. 19, for regular and frequent inspection of hydrants has been complied with. No. 18, for a change in hydrant threads has not been complied with but that would have to be done in conjunction with a change of hose thread by the fire department. That is not so important in Denver as in cities located close together where aid may be exchanged in case of fire. The system of reducing pressures below the pump station at Capitol Hill was giving satisfactory service within that district in 1910. The minimum pressure in the whole gravity district in 1910 was 16 pounds. In a number of instances in the fire flow tests it was impossible to find hydrants properly located to enable us to take pressures on the arteries feeding the groups. One test showed 7 pounds, another 6 pounds, another 9 pounds, another 3 pounds, another 5 pounds, and another 2 pounds, remaining on the mains with the hydrants discharging the quantity of water obtained. The reference to 4 inch mains or long 6 inch mains unsupported failing to give sufficient water supply refers to mains in the outlying districts, which have not yet developed sufficiently to warrant the laying of large feeder mains. Of the 2719 hydrants when owned by the water company, each generally had one 4½ inch connection for
278 fire engines and two 2½ inch connections for either hose or fire engine.

Redirect examination by Mr. Dorsey:

Extracts from report of 1910 of the National Board of Fire Underwriters contained in Exhibit C. at pages 11, 13, 38, 41, 45-48, and Plates 7-a and 7-b admitted in evidence over objection by defendants. (Objection sustained as to statement from said report at page 50, as follows: "The water sheds are ample in capacity and have been developed in advance of the growth of the city, over two years supply at the present rate of consumption being now held in storage." On the ground that witness had not shown himself qualified). In the course of such inspections particular attention is given to the source of supply and its development. In Denver I had access to all records of stream flow and rainfall which were then available for the entire watershed. I also visited the water sheds at Cheesman Reservoir, Marston Lake, the intake works on Bear Creek, on the Platte River and made computations from the records on Cherry

Creek. Have made similar examinations as to most of the other cities that I have inspected, also of the Massachusetts Metropolitan Water Supply. Many of the cities I have examined are in arid or semi-arid regions.

Recross-examination by Mr. Nye:

I should say that I went up Bear Creek about a mile above the intake or about 9 or 9½ miles above Marston Lake, and did not go up Turkey creek. I did not go up the North fork of the Platte. I did not go up the South fork of the Platte between the junction and Cheeseman Dam. But I observed such of the water shed of Lake Cheesman as could be seen from the surrounding mountains and the water shed in South Park in the neighborhood of the Antero Reservoir a good many miles above Lake Cheesman. I gave more weight to the stream flow records which in Denver are exceptionally complete, than to the observations that I made. I did not take into consideration the question of water rights. I observed as much of the water shed of Cherry Creek as could be observed from the Colorado & Southern railroad running out of the city along the creek. (Ruling on admission of statement changed and page 50 admitted. Defense excepts to first sentence.)

Redirect examination by Mr. Dorsey:

(Page 49 of Exhibit C, excluded by agreement of counsel.) I do not recollect how far out Cherry Creek I went. At the time of the inspection of 1910 Lake Cheesman was practically full.

In the inspection in 1910 I had recourse to the United States topographical maps of the territory. I was in error when
279 I stated on cross-examination that I had not gone up the North fork of the Platte. I did go there going to Lake Cheesman.

The Hazen and Williams Formula used by me in computing the capacity of the conduit lines is a generally accepted formula much used by engineers. The pressure tests made on the system independently of the fire flow tests were made without the presence of any representative of the water company. The work was done by an assistant who was driven about town in a buggy by an employe of the water company. The aggregate total capacity of the conduits left in service after the break was 66,000,000 gallons. The conduit furnishing the supply for the West Denver Station inquired about on cross-examination as a supplemental supply is one of the conduits out of service, therefore that supply is not available. In determining the sufficiency of a system for fire protection purposes we take into consideration the maximum day's consumption because the capacity of the system must be in excess of this maximum rate. A fire may occur on that day.

In as much as the accident to these conduits was an unforeseen act of nature which can be guarded against in the future by suitable construction at small cost, the occurrence has not changed my opinion as to the reliability and capability of the plant for the pur-

poses to which it is put. It is impossible to so design a waterworks system that it cannot be put out of commission. The works in Denver allow a safe margin. It is possible that all of the conduits would go out at once but not at all probable. The probability is much more remote than if they were fewer in number. I know of no city in the country in which it is not possible for the whole water supply to be taken away through a possible combination of circumstances. (Objection overruled. Exception.) Accidents to large cast iron mains in Boston have caused more serious reduction in the supply over large areas than was caused in Denver. The interruption in Dayton was caused by high water in the Miami River. The precautions which had been taken to prevent damage from that cause were insufficient. In the case of San Francisco the damage was due to the earthquake. San Francisco has been subject to earthquakes ever since there has been a San Francisco. It would be my opinion that a flood in the Miami River would be just as much to be anticipated as a flood in the Platte. And I should say that an earthquake in San Francisco was more to be expected than a flood in the Platte. Substantial dikes that will prevent a recurrence of the flood damage in Denver can easily be provided.

I stated that the West Denver Station supply was not vital on the theory that it might be out of service temporarily and
280 still leave sufficient supply for the city. But it is operating as a part of the system and if it were not there we would not consider the works satisfactory as there would not be sufficient reserve provided. The West Denver station should be continued as part of the system and operated as it was in 1910. All hydrants in the congested value district furnished a satisfactory supply of water notwithstanding the fact that some of them are connected to the smaller main in the street where two mains exist.

Redirect examination by Mr. Dorsey:

In referring to that portion of the Capitol Hill high service where the pressure is reduced, below the pumps, I meant that portion of the service lying west of the pump station, below the elevation of the pumps and independent of the main gravity service. The 30 pounds is immediately below the reducing valve and as the elevation reduces the pressure increases. The minimum pressure of 16 pounds mentioned was the lowest pressure observed anywhere on the main gravity service. The pressures indicated in columns X and Y in the fire flow tables were both taken while the hydrants in the particular group were open and flowing. In selecting the locations for the tests particular attention was paid to pick out the weak points in the system. Other tests were run at the strong points to determine the capacity of the arterial feeders. The drop in pressure in test No. 9 was due to the fact that there was no large main feeding that group. The same is true in test No. 12. In test No. 13 the difficulty was caused by the gridiron being formed principally of 4 and 6 inch pipe. Test No. 16 the difficulty was caused by the inability of a single 6 inch main to supply the quantities desired. The same is

true of test No. 22. Test No. 23 the difficulty was caused by the 4 inch pipe in Globeville where the pipe system is owned by the City. Test No. 25 the difficulty was due to the hydrants being located on 6 inch mains extended from 6½ to 8½ blocks without support. In test No. 9 the pressure with the hydrants closed was 85 pounds. In No. 12, 63 pounds. In No. 13, 71 pounds. No. 16, 90 pounds. No. 22, 42 pounds. No. 23, 85 pounds. No. 25, 62 pounds. These particular locations were picked as the weak spots on the system, though the pressures were generally higher than the average. If the tests had been made a short distance from the locations selected in each case a greatly increased quantity of water could have been obtained.

In the congested value district direct hydrant hose streams can be used up to and including the 4th story of a building. At the time of the report about 75 per cent of all the buildings in the dis-
281 trict were 3 story. Even when the maximum quantity of water was being drawn sufficient pressure remained on the system to cope with fires in three story buildings and put out fires spreading from flying embers. The pressures in Denver are better maintained under heavy draft through the whole system than is the case in the other cities which I have inspected.

Recross-examination by Mr. Nye:

No material benefit would be derived from opening the valves from the Capitol Hill High Service to the gravity service, the greater pressure from the high service would quickly be dissipated in the gravity mains. The pressure in the congested value district could be increased in case of fire by opening the valve connecting with the North Denver gravity service, or by speeding up the pumps at West Denver. It is essential to maintain the pumping capacity of 18,000,000 gallons at West Denver to utilize 12,000,000 gallons of water per day. My statement that hose streams could be used up to four story buildings in the congested value district is based upon actual experience and experiment with hose streams under varying pressures. I attended only two fires while in Denver and made no tests at either. I never heard of a fire in Denver where the stream supplied by a fire engine failed to reach the second story. If that did occur I would want to know the hydrant to which the engine was attached and the condition of the engine before expressing an opinion. There are many conditions that enter into the use of water by a fire department.

Though better conditions could have been obtained in the fire flow test immediately adjacent to the tests enumerated as not satisfactory, there was a deficiency at the point where these tests actually were made. Reducing valves reduce the pressure without materially affecting the flow of water. We determined the effect of the valves in Denver by the tests. The tests were taken under normal conditions because the pressures at the time of the tests corresponded with the pressures previously taken on the system. If there were opportunity and time men and material enough at hand the flood

damage probably could have been prevented by a temporary dike of sand bags. I don't know what conditions prevailed prior to the damage.

The flood at Dayton and the earthquake at San Francisco were certainly more serious than any that had been previously experienced in either place. I have not changed my opinion as to the sufficiency of the capacities, cross connections, etc., of the 6 conduit lines as expressed in 1910.

Redirect examination by Mr. Dorsey:

I have made numerous investigations on specific hydrants and in specific localities where shortages of water for fire purposes
282 have occurred, to determine their cause. The results obtained and the opinions formed are based upon well settled hydraulic principles that apply equally as well in Denver as elsewhere. The amounts of water required under the standards of the National Board are the maximum amounts that could be required under any circumstances. Such amounts are not required at every fire. I am not informed as to the efforts that were made to protect these conduits against the flood damage. I observed that a dike had been constructed near the failure of the Mississippi Street conduit.

There had been frequent floods at Dayton before the flood that put the works out of commission and there had been previous earthquakes at San Francisco. The recent flood in the Platte river was unusual from the fact that no such stream flow has ever been recorded previous to this flood. I will forward from Boston a copy of the National Board report on Denver for 1910.

Witness JOHN R. FREEMAN.

Direct examination by Mr. Dorsey:

I reside at Providence, R. I. Am a civil engineer making a specialty of hydraulic work, municipal water supply and water power. I obtained my technical training at the Massachusetts Institute of Technology. Am 59 years old. (Qualifications.) (Principal activities: Engineer member of Metropolitan Water Board Massachusetts. Board of Water supply of New York City. City of San Francisco. Baltimore. City of Mexico. Hartford. California Gas and Electric Company. United States Reclamation Service. Mexican Northern Power Company. Great Northern Power Company. The Canadian Government. Mississippi River Power Company. City of Los Angeles. Aggregate cost of works more than $200,000,000. Am familiar with structural costs, values, and depreciations in respect to water works property, and with the financial management of public utilities. Was a member of the board of appraisers appointed in 1907 to appraise the property of the D. U. W. Co.

Was a member of two different boards of engineers in connection with the construction of the Panama Canal. The first to devise foundations of the locks and the Gatun Dam, the second to report on the relative merits of the sea level and lock canals. Those boards were appointed by the President of the United States. Mr. Stearns

who represented the City of Denver on the Board of Appraisers was a member of both of those commissions and Mr. Harrison who with me represented the company in the appraisal was a member
283 of the second board. We were appointed on the Board of Appraisal sometime in October of 1907. Came to Denver early in November, remained here nearly the entire month when some of us were called back to New York, returning to Denver again in about a week and remained nearly through the month of December. Most of our deliberations were carried on in New York because of the illness of Mr. Harrison who was suffering from heart trouble. Mr. Harrison was formerly chief engineer of the D. U. W. Co. and had charge of the design and construction of Cheesman Dam. He was later assistant chief engineer for the Pennsylvania R. R. Co. on the construction of the tunnels under the East River and later deputy chief engineer of the Board of Water Supply of New York City.

Prior to his connection with the D. U. W. Co. he was assistant chief engineer of the Isthmian Canal Commission and assistant chief engineer of the Deep Water Ways commission investigating canal routes from the Great Lakes to the Ocean. Prior to that was in charge of construction of storage re-servoirs for the control of the head waters of the Mississippi River and resident engineer on the Chicago Drainage Canal. He was an exceptionally able engineer of the highest character and standing. Copy of the Report of The Board of Appraisers and Arbitrators on the value of the works of the D. U. W. Co. attached to the bill of complaint appears to be an accurate copy of our report submitted March 20, 1909, on which we began investigation November 1907.

We made a most thorough investigation of all details, a careful inspection of all visible parts of the plant, were furnished with complete plans of the works, had special plans prepared to show some parts more fully, took a great deal of evidence on the question of water rights, value of lands, real estate, etc. Both parties were represented by Counsel. In every way we sought to become as fully informed as possible on all matters bearing upon the case. It is my judgment that the efforts made put us fully in possession of all facts necessary to form a fair judgment of the value of the property. The value found was $14,400,000., as of December 31, 1907 or January 1, 1908.

I have examined Exhibit C. and am convinced that it is an inventory of the property valued by us with additions made since that valuation. The valuation of $14,400,000 was divided into three parts. Physical property, $10,354,075. Water rights, $2,845,925. Business and going concern, $1,200,000. $100,000 of this amount was for the value of company business during the remainder of its franchise period and $1,100,000 for going concern value entirely independent of any business and franchise value.

284 In addition to valuing the property of the D. U. W. Co. we valued certain property owned by the City of Denver, chiefly composed of the water system in South Denver. A list of water rights contained in the report of the board was furnished by Mr.

Miller Secretary of the D. U. W. Co. From page 11 to page 16 of report appears a list of city real estate valued by Victor R. Olmstead representing the city and William W. Watson representing the company. These valuations were adopted by the board of appraisers.

At pages 17 to 24 of the report appears a list of real estate outside of the city valued by J. B. McNeil representing the city and Burton D. Sanborn representing the company. Their valuations were used as a basis for determining the value of the lands for water works purposes. At pages 25-28 of the report appears a table agreed to by J. B. Hunter City engineer and W. F. Hawes representing the D. U. W. Co. setting forth the lengths of mains, number of valves, hydrants, etc., composing the system. At page 29 occurs a table agreed to by said Hunter and Hawes giving similar information concerning the works owned by the city. On page 31 begins a report on the value of personal property, furniture, tools, etc. owned by the company, agreed to by C. F. Read representing the city and A. E. Hamilton representing the company. Their values were adopted by the board.

At page 34 begins an inventory of the material at the West Denver Pipe Yards, agreed to by Mr. C. L. Harrison, member of the board representing the D. U. W. Co. and Mr. Stearns, representing the city. At page 45 appears a schedule embracing all other physical property valued by the board. The $100,000 valuation for business value related to the possible earning capacity of the plant for the two year unexpired period of the franchise. Otherwise the board gave no consideration of the earning power of the plant in arriving at its valuation. In general reproduction cost less depreciation was the basis of valuation.

I am not clear as to where the line is drawn between the properties of the D. U. W. Co. and the S. P. C. & R. Co. but we valued the property of the two companies as a unit system, without regard to division. Exhibit X is a diagrammatic sketch on a distorted scale showing the location of the six supply conduits which bring water to the city. Exhibit Y. is a diagram-atic sketch of the elevations of the different reservoirs and the elevation of the sources of supply and filtration works, also the relative elevations of the different supply conduits.

"General description of the system, handling and method of operation of the same." Cheesman Dam is one of the very finest masonry dams in the world. I know of no other dam that
285 is its equal in water-tightness. From the view point of desirability and economy of construction the site is the best I have ever seen anywhere in the world with one possible exception, in California. I know of no other reservoir used for domestic water supply that is so desirable. The construction of the new conduit to supply Marston Lake has greatly increased its utility. It is a very desirable and very valuable part of the works of the company. The connection with the Platte River through the new conduit, has greatly increased its value and also increased the value of the water rights of the company through permitting them to be used more efficiently, and through permitting more effective conservation

of the water supply. We gave very careful consideration to the distribution system. I consider the duplication of mains in the congested value district of distinct advantage and value to the system. Though the valuation allowed for those duplicate mains was less than 1-50th of the valuation allowed for the entire distribution system.

A further value of Marston Lake arises from its elevation which is greater than any point served in the city and from its convenient location which will permit of the construction of future filtration plants there at less distance from the city than any of the existing plants. There are certain difficulties connected with the water supply in Denver that usually are not presented all together in other cities. The difference in elevation requiring the division of the system into high and low services, the uncommonly large quantity of water demanded by the consumers and the fact that the city is located in a land of very little rain and great variation in stream flow which shrinks to insignificance during the latter part of the summer and fall and necessitates carrying a much larger quantity of water in storage than is usual in cities that are required to provide storage reservoirs by reason of taking of their supply from streams of varying flow. The population of Denver is also badly scattered, greatly increasing the expense of the distribution system. The population and number of taps per mile of pipe in Denver being relatively small and the cost of the distribution system per capita relatively large.

The reserve storage provided in Denver is greater than in any other city in the country with the possible exception of San Francisco, but it is not excessive. The D. U. W. Co. has not made provision for growth and extension too far in advance of its present condition. The use of 6 supply conduits is a good feature of the works and tends to make them more safe against interruption of the supply. The wood stave construction is entirely proper. There are some relatively small articles of no great value which are not indispensable in the operation of the system but substantially everything
that I have seen in the structures, supply yards or inventory
286 are proper and useful in a water supply plant. The Board of Appraisers valued the lands and structures at Lake Cheesman at $1,955,000, lands and structures at Marston Lake, $673,805. The distribution system at $3,850,165. The personal property including furniture, fixtures, and material on hand at $328,053. Probably more time was devoted by the Board of Appraisers to a discussion of the value of the water rights than to anything else connected with the system. Mr. Stearns did not agree to the valuation for water rights finally found by the board. In the final value no definite sum was fixed for the several rights, they were considered more valuable assembled as a whole than as divided parts.

I have not considered whether the water rights are more valuable today than at the time of the appraisal but my personal judgment at the time of the appraisal was for a slightly greater value than was finally agreed upon. There were certain properties of the company, principally ranch land, acquired in connection with water

rights that were held in reserve against future need for the utilization of such rights until they should all be needed for the benefit of the city. This is also true of the water rights of the Littleton grist mill, control of which gave the company more efficient control over the priorities of the Platte Canon Ditch. We allowed a very small value for the so-called Strong Reservoir site. It was my understanding that it was acquired before Lake Cheesman to serve a purpose somewhat similar to the purpose for which Marston Lake is now used.

In the future it may become useful in connection with future water rights from Lake Cheesman. It is a very good reservoir site and can be given great capacity at a relatively small expense. We allowed a very small value for Sullivan Reservoir, much less than reproduction cost. It is well suited for supplying the eastern portion of the city by gravity when it is needed in connection with the growth in the Capitol Hill district. I do not believe that the water company has gone beyond the proper practice in acquiring and holding such property against future need. Going concern value is the added value attached to a live system over a dead system. It has no reference to the element of franchise or good will. The going value of this plant is as great today as when we appraised it. To bring the 1907 valuation down to date it would be necessary to add additions since that time, deduct the value of the parts separated from the property and deduct depreciation that has occurred on the property previously appraised and since added. I have obtained from the company a statement of the additions since the appraisal and subtractions from the plant. To check the details of the extensions, I have had the chief engineer prepare a map of the
287 system which I might compare with the map prepared for us six and one-half years ago.

From that and from inspection of the visible property I have concluded that the amounts charged for those additions, are proper and reasonable charges. The detail of these charges is shown by Exhibit Z. In addition to the expenditures shown by Exhibit Z. I have added 17½ per cent for overhead charges and interest during construction which I consider a very moderate allowance for work done piecemeal and scattered over a number of years. I was informed that the only separation from the property which we had appraised was real estate which had been sold for $39,777.90. I found the total cost for net additions to the plant amounted to $1,970,892.74. In addition to my judgment that the charges for these additions are reasonable, I am supported by an estimate made by our board that expenditures to the amount of about two million dollars would be necessary to keep the plant up to the demands of the city during the period involved.

Taking into consideration all of the elements necessary to be considered it is my opinion that the value of the plant based upon the 1907 appraisal brought down to date is $15,370,000. I have not attempted to put a money value on the increase in the value of water rights. Though I am of the opinion that they have increased in value and that an increase has been effected by the connection between the Platte river sources and Marston Lake.

I think the method adopted is equivalent to the reproduction cost less depreciation method, the costs involved being so recent as to be the most convenient measure of such cost. I have given very careful consideration to the question of depreciation on these works. The board of appraisal sought to find for every important element of these structures the remaining useful life. We found after such examination that it would be necessary, to make good, the then value of the physical structures to put aside the sum of $134,000 a year. This amounted to 1.625 per cent on the value of the then existing plant on which interest must be earned at the rate of 5 per cent per annum compounded to make good the structures upon the expiration of the estimated useful life. That depreciation allowance is independent of the charges for ordinary maintenance, repairs, and renewals. I estimate that a fair allowance for depreciation of the present plant is $168,112. This annual depreciation is the amount by which the property devoted to public use will each year be lessened in value by its dedication to that use. This depreciation allowance is for the normal depreciation and does not take
288 into consideration the abnormal depreciation that will result if the city constructs a competing system, within the next seven years. To make good that abnormal depreciation it would be necessary to more than double the existing leaflet rates. (Objection to this line of question overruled. Exception.)

In ascertaining the accrued depreciation at the time of the previous valuation we depended upon the average judgment of the board. We were able to see the structures and see what had occurred so there was no necessity for adopting a method like the sinking fund method. In estimating the future depreciation we employed the so called sinking fund method, which in my judgment is the most proper and approved method for estimating future depreciation. If we had adopted the straight line method the annual charge for the next five or seven years would have been much higher than estimated by me. In computing the depreciation accrued since the appraisal I arrived at the sum of $900,000, which I deducted from the amount of the appraisal plus additions. I believe that the sum of $350,000 a year would be a fair allowance for the ordinary operation and maintenance expenses exclusive of taxes, and depreciation on this plant for the next four or five years.

The fact that the number of miles of pipe required in Denver to reach a given number of consumers is exceptionally large and that the per capita consumption of water is very large would necessitate a higher schedule of rates than would be necessary in the average city.

Cross-examination by Mr. Nye:

I have devoted to a study of this situation not less than 100 days in 1907, 1908, 1909 and from 15 to 20 days during the present year. I reached the conclusion concerning which I have testified, last week, though I may have made a few computations this week which I took into consideration in my testimony. It is difficult to say absolutely what portion of my work in preparation for this case consisted of original inquiry and what part applied to connecting up with the

previous valuation. I reviewed the data collected by the board of appraisal entirely independent of the conclusions reached by that board. I would say that I have reached a new determination, having under consideration the old determination, but which in a sense is independent of the determination of that board. The two inquiries have been so closely interrelated, having both the old and new data in hand, that I would not attempt to say what portion of my consideration had been devoted to each class. The new data consisted of various facts contained in exhibit C. and the report prepared
289 in part by Mr. Fellows. Prices were not extended in the particular copy of Exhibit C. that I had but I have seen some values that have been extended by the parties who prepared that inventory. I am connected with several companies that have money to invest. Some of these investments are in corporations operating under franchises, I do not now recollect of any investment in securities that run for a longer time than the franchise. In general my determination of the value of the physical plant took into consideration the same elements that were considered by the board of appraisal.

The board of appraisal considered original cost as one element, other elements were increase in the cost of labor since original construction, the difference in cost of cast iron pipe, and in fact, took into consideration every element that we could reach. The cost of reproduction was what we endeavored to reach. In some cases as the starting point toward that we took original cost. In the recent determination I have tried to follow the same methods.

I will endeavor to supply you with such original cost data as I have in my possession. It is very fragmentary in form and incomplete, however, and merely in the form of memoranda. I did not state that I had recently made an entirely independent and complete estimate and determination. I relied in part on the previous determination. I cannot recall that we ever had before us the price paid by the D. U. W. Co. for the property acquired in 1894. In some cases we called for vouchers on original cost and were furnished with whatever information we requested. The allowances for interest during construction, engineering, contingencies and general expenses, were our estimates of what those items would cost to reproduce this plant based on the costs that I have found by experience are actually incurred. In arriving at my recent determination I did not attempt to go through exhibit C. and value the items separately. Our board had similar lists before it. In some instances in the previous valuation I estimated the values in detail, in other instances I took certain structures, buildings for example and estimated the value by applying unit cost to the area or contents.

The figures that I arrived at were frequently not the figures determined on by the board. We arrived at our conclusions after more or less debate on many items. In my recent determination I reached the same figure for the value of the property as of January 1, 1908, as was reached by the board of appraisers less $100,000. That being the allowance for business value, which I deducted. I

used the same classifications as were used by the board of appraisal.

290 We accepted the valuation placed upon the land outside of the city by McNeil and Sanborn as a basis showing the agricultural value of the land but not as purporting to show the value for water supply purposes. The board did not always agree on various items. One member would be high on one thing and another low on another so that the result on the total was easily harmonized though agreement was impossible on individual items. The element of connection with a domestic water supply entered largely into the final determination of the value of lands outside of the city. No agreement was reached on any final schedule into which the main items, A, B, and C, making up our total valuation could be subdivided. Sometime before his death, Mr. Harrison turned over to an official of the water company a statement containing his personal notes and conclusions on various items of the property. This was done without my knowledge and I never submitted any figures for it.

I have a copy of it in my case of papers but I do not recall having turned to it while testifying. I made notes on it in connection with my recent determination. (Argument by counsel over the right of Mr. Nye to examine pamphlet in Mr. Freeman's possession. Master withholds ruling to examine record to ascertain whether witness referred to pamphlet.) I will produce copies of such figures as I may have relating to original cost of parts of the plant.

Mr. Nye reads from pages 741-742 figures purporting to be figures read by Mr. Freeman from the pamphlet under discussion.

Examination by Mr. Dorsey:

I did not refer to such a pamphlet while being examined concerning the appraisal by McNeil & Sanborn to which Mr. Nye's request of this morning was addressed. When examined concerning those matters I was referring to the pamphlet already in the case which is now before Mr. Nye.

Master rules that Mr .Nye may interrogate concerning any particular page or pages referred to by the witness in giving his testimony.

Cross-examination by Mr. Nye:

Referring to the data from which I gave the figures $1,955,000 as the value of Lake Cheesman I have it here in two places, one in a memorandum by M. L. Holman of the board of appraisers and another in the copy of Mr. Harrison's notes. I may have referred to either of these sometimes one and sometimes the other.

291 From my other notes I checked off on these certain figures in order to bring them into more compact form as a matter of convenience. (Shows markings to the Master.) The Holman memorandum was more convenient to refer to because the figures are right side up as I hold the book. The others are printed at

right angles to that direction and not so easy of reference. In regard to the value of material in the material yard I referred to some ink notes written on the copy of the Harrison notes, because at that point the Harrison notes were incorrectly printed, and I used notes of my own. When I testified concerning the amount of $10,354,075 I think I referred to the brown pamphlet entitled "Report of the Board of Appraisers and Arbitrators" and not at all to the so called Harrison pamphlet. In referring to the item of $328,053 of personal property I have no doubt that I referred to the Holman memorandum, because it is more easily legible in that than in the Harrison memorandum. It is not true that I arrived at a valuation of $14,400,000 for the entire plant then deducted from that the valuation of the physical property and going-concern value to find the water right value. My conclusion was that the property was worth a somewhat larger sum than $14,400,000 but after a great deal of debate I agreed to sign the report on that total.

I don't remember exactly how the final figure was reached, except that we were several days figuring and arguing and finally got together on that figure and the other figures too. I distinctly differed in many of the items with the Harrison memorandum, but I used the total figure of the original appraisal in my conclusion. I made no deduction for the amount $12,000 allowed by the board of appraisers for the unexpired term of the lease on the company's office.

This item was contained in the valuation of city property by Olmstead and Watson and I did not attempt any revaluation of it. The only item that I eliminated was the $100,000 for business value. We did not use ten per cent of the value of the physical property as the going concern value, though it checked out about 10 per cent. My own valuation for going concern was considerable higher than 10 per cent. I think that going concern value applies with equal effect to a practical monopoly, like the water company, as to any other business. The board of appraisers was considering value for both purchase and rate making purposes.

The fact that the franchise was to expire in 1910 had no bearing on the allowance for going concern value. I think we figured interest at 4 per cent for the average period, though I have a note here June 7, 1908 figured at six per cent and have other notes of different rates. Each member of the board had different figures for
292 interest during construction. I find that my notes fixed a total of $893,000 as a proper allowance for interest during construction on the reproduction cost of the plant. I find allowances in my old notes of 15% for engineering, contingnecies and general expenses on various items. In my present allowance I figured 15 per cent, for engineering, contingencies, and general expense and added 2½ per cent as the equivalent of interest during construction. This percentage was applied to the original cost of material and labor since the appraisal. In estimating the future depreciation at the time of the appraisal I wanted to provide for $150,000 per year but finally agreed upon $134,062.

(Statement of remaining useful life of certain items of the property.)

In making the appraisal we did not determine the useful life of the various items from the date of construction but determined the remaining useful life from the date of the appraisal. Some of the structures on which we then considered the depreciation have since been entirely replaced by new structures. I took that into consideration in adopting the allowance of $900,000 as the accrued depreciation since the former appraisal.

In estimating the remaining useful life of the various useful items of property we had before us the actual years of use in every case on which to predicate average judgment as to the remaining life. We estimated at that time 8 years of useful life for the Willard Filters. I do not believe that new filters could be constructed at less original cost than those filters and operated at half the cost. In fact, I have been surprised at the low cost of operation on those filters. My judgment now is that those filters were worth more than we allowed for them in 1908, because of the discovery of the hypochlorite process. There is a discrepancy between the reservoir capacities given on exhibits X & Y, probably due to the fact that the reservoirs are operated at different levels than formerly. It is not true that Cheesman Dam is designed and constructed more heavily than is necessary for the purpose. Were I designing it today I would use substantially the same dimensions.

I think the city of Denver could be supplied from these sources without the use of Lehow Lake, but I think it is worth the small value that we allowed for it. Considering the many elements in the plant entirely independent of everything else, there are a number that are not essential in the strictest meaning of that word but if you lop off first one thing and then another the condition is very different. If Denver has stopped growing then the lopping off process might be carried farther than if it is still growing, be-
293 fore you reach the point where a particular element could not be dispensed with. If the City grows out beyond the Mississippi Street galleries they may go out of commission from that cause. The Sullivan Reservoir is not essential but it has a potential value equal to the amount that we allowed, which is the amount that I allowed in my present determination. The new construction to Marston Lake increases the value of the plant as a whole through permitting more of the Platte River water to be utilized.

The question of going concern value is a matter of judgment rather than a matter of precise computation. I consider that the allowance made by the board was fair and I consider it fair at the present time. That it approximated 10 per cent tallied in a general way with my past experience. The original valuation was for rate making purposes as well as purchase. The depreciation table that I have contains simply the assumed remaining years of useful life of the property with the valuation that we found for it at the time. It does not state the expired life or the gross reproduction cost. I have the original cost in some cases, in many cases no. In making the determination of value I did not take into consideration the

stocks and bonds of the D. U. W. Co. I do not think I knew what the stock and bonds were until sometime after we had made this computation. I do not know that the valuation found was approximately the market value of stocks and bonds. I have not the figures of gross reproduction cost here.

In many of these matters we examined the property and exercised our judgment as to what it was worth at that time. The ultimate conclusions as to present value are the only figures I have. The figures contained in the Holman memorandum are practically the figures used by the board of appraisers in fixing the final value. The board of appraisers took into consideration the item of pavement over mains. I have the figures for pavements I used myself but not the figures used by the board. I am not sure that we came to a separate agreement as to the amount to be allowed for pavement. In my present determination I considered it and concluded that the amount if different at all would be larger than it was at that time, so I did not go back into the detail. We had a good deal of discussion over the duplicate and triplicate mains. No allowance whatever was made for the triplicate mains and I think 50 per cent depreciation was charged against the duplicate mains. The total allowance for duplicate mains I think was only $66,000 out of a total of $3,602,000. The depreciation charge covered both the depreciation and obsolescence. I presume our reproduction cost was based on reproducing the duplicate and triplicate mains. I cannot conceive that we would have taken it any other way. I
294 should not consider that it would be reproduction unless we did follow that way. I cannot recall that we figured any extra cost in going beneath street railway tracks.

I cannot now recall that any allowance was made in the going concern value for the expense of developing the business. The fact that the company had paid three dividends did not enter into any estimate that I made of going concern value. I based my recent estimate upon the same elements as I based my estimate in 1908. Regardless of the fact that the city is about to begin construction of its own plant. I believe that the value is there if the city chose to avail itself of it. I believe that the construction of such a plant by the city would depreciate the present plant at least $10,000,000. I did not take that into consideration in determining the present fair value of the property. I presume that the city can build its own plant if it wants to, but I believe that it is impossible to do so at the price stated.

I understand that the D. U. W. Co. has been without a franchise for four years and the people have refused to grant it a franchise. It does not necessarily follow that any of that $10,000,000 depreciation has accrued. I believe that the value is as I have estimated it and I think when the citizens realize what a duplicate plant will cost that they will buy the present plant rather than spend possibly $20,000,000 in building and undergo the tearing up the streets incidental to laying new pipes and afterwards taking out the old ones. These facts had nothing to do with fixing my present valuation. They were simply brought out in answer to your question. Defend-

ants exhibit 1 seems to be a correct copy of a pamphlet that I have in my notes, known as the Harrison notes. The last item on page 8 reads property not in use for water works purposes, mostly lands, $174,870.00 I included that in my valuation for rate making purposes because I consider that it was used for water works purposes. There are several other statements in that circular that I think are inaccurate. On page 9, are certain figures as to water right values that certainly are not figures that I have used or would accept. I think the values set down for the lands at Platte Cañon intake works $3600 were tentatively agreed on by the board. The value given by McNeil and Sanborn for pasturage was $765. We valued it for waterwarks purposes. My own valuation was $5,000. I was not always the high man on the board.

Pamphlet shows $7,500 for Platte Cañon filter lands, McNeil and Sanborn $2,760. We were valuing for waterworks purposes, they for dry farming. McNeil and Sanborn did not value the
295 Platte Cañon Reservoir, submerged land. 3.22 acres in the Filter site was valued by McNeil and Sanborn as land in its original condition. The board valued it at $1,500 for waterworks purposes.

I do not believe that the pipe bridge that we valued at $6,000 could have been reproduced for anything like $2,500. Taking Defendant's Exhibit 1, right through it substantially represents the values agreed upon by the board.

I have said repeatedly that we did not arrive at the water right value by first agreeing on the total value and then deducting therefrom the physical value and the business and going-concern value. We valued the property as though the title were in the company, assuming that all question of titles would be settled. My best recollection is that we paid no attention to original cost of water rights any more than we would have considered that the filing fees represented the present value of a valuable mining property. We allowed no value for the item of service connections. Exhibit Z was made up for me. I did not ascertain independently of that exhibit what bonds had been disposed of or the total value of bonds for which discount was claimed. I considered at all times in valuing the property the element of value for the purpose of a municipal water supply for Denver. I believe that ownership of the power rights of the Littleton mill give the company a more efficient control of water for the Platte Canon ditch.

We had several tables of unit prices on the pipe lines. The price of pipe at the time of our appraisal was rather high, averaging I think $41 per ton. We allowed I think $35 per ton because we felt that the prevailing price was abnormally high. Defendant's Exhibit 3 is a copy of a tabulation of unit prices used by the appraisers on cast iron pipe. The cost of laying pipe and the pavement over it are determined together. My recollection is that we had a table of unit prices for wood pipe but I have not been able to find it among my tables. In my recent determination I took into consideration the fact that there had been a decrease in the cost of cast iron pipe but concluded that the increase in the cost of labor would just about offset

this decrease. So I let the old figures for the distribution system stand with the allowance for depreciation that I have mentioned.

I made the statement that the functional depreciation in this plant due to the construction of a new plant by the city would be about $10,000,000 as an appropriation. That would leave a junk value on the basis of my figures of approximately $5,370,000, consisting of lands, water rights, large pipes not under expensive pavement,
pumping engines, etc., I had given the matter consideration
296 before I went on the witness stand. I assigned the salvage
value in a rough general way. That is why I stated the figure as a round sum without making it precise. The method as I now recall was to estimate the probable junk value in round numbers. It is true in my judgment that the all-year-round use of the water supply of the D. U. W. Co. gives the greatest portion of the value to its water rights. The all-year-round use as to the reservoir water would not be affected by the city constructing a new plant and developing a new water supply. As to the other rights, some question of intermittent use might come in.

The all-year-round use of the water rights does not enter into the question of going concern value. The estimate that I made of $350,000 a year for operation and maintenance exclusive of taxes and depreciation is based upon judgment and upon an examination of the operating expense record of the company. It checked also with my judgment of about 25 per cent of the gross revenue for operating expense. I estimated that all current or ordinary repairs would be made out of the amount charged to operation and maintenance. Maintenance and depreciation are rather closely allied and not easy to distinguish. I do not believe that the depreciation allowance that I made is sufficient to cover all necessary maintenance as well as depreciation.

Redirect examination by Mr. Dorsey:

While I was engaged for more than 100 days on the valuation of the plant in 1907-8-9 the other appraisers were similarly engaged. The inventory of the plant was practically done for us when we arrived in Denver, so we took it around with us as we went about the works and I entered on my copies my own judgment as to the various features. As to many items of the inventory they were agreed upon between representatives of the city and representatives of the company before they were submitted to the board. The detail work of the board was divided up between the different members acting as committees.

The report of Mr. Fellows to which I referred as having had access to was the report of the board of engineers of the Public Utilities commission on the plant of the D. U. W. Co. By reproduction cost I mean the cost of reproducing a structure equally as good for the purpose or in some cases the same structure at the present time and the present prices of labor and physical condition. The elements of the plant on which we had original cost data were the Cheesman Dam, the pumping stations, and certain contracts for cast iron pipe. The original cost data was used in regard to such matters as the

tunnels under the dam at Lake Cheesman the fence around the reservoir the telephone lines, and various matters of that
297 kind, and due consideration was given to changes in the price of labor, etc. The duty of the appraisers under the ordinance authorizing us to act was to return merely a total valuation, not an itemized valuation. We made the separations that we did simply as a matter of convenience to the interested parties. The Harrison notes were not in any sense a report by the board of appraisers. Regarding the item of $12,000 allowed for the lease of the company's offices I have been told that the lease had been extended.

My judgment of the fairness of the allowance for going concern value was fortified by the fact that it checked out about 10 per cent of the value of the physical property. That is the average result obtained in valuation. I have awarded a much higher per centage however. I have no clear recollection of any allowance less than 10 per cent. When the board of appraisers allowed a valuation of $100,000 for business value they did not know that the franchise of the company would not be extended. Interest during construction would vary in time for which it was allowed as applied to various and different constructions. My recollection is that my figures for interest during construction were $893,000 and the board finally agreed upon $850,000. Engineering and contingencies are proper allowances in estimating reproduction cost. My figures for these were based upon 15 per cent but if I were doing it over again I should adopt a higher figure in view of my experience in the last half dozen years. The mechanical filters are doing better work today than they did in 1908, due to improvements in the art of filtration. I added no distinct increase in value to the former appraisal because of the increased value and utility of Marston Lake or of the water rights. The recent investigation was somewhat hurried and I thought that ignoring that increase would offset any possible error or oversight in depreciation or separation from the property. It was my purpose to be conservative.

Have stated that conditions surrounding the supplying of water in Denver are unusual as to abnormal consumption, variable and extremely small stream flows and excessive mileage of mains for population served. These conditions have to be met. The appraisement of 1907 was for two purposes, purchase and rate fixing. In that valuation the board made an allowance for paving over mains. Anyone reproducing this plant would have to go through these pavements in order to lay pipes. I think it is the proper practice. Pavement laid since the appraisal would increase the reproduction cost. I allowed depreciation on those pavements in the same manner as on the pipe. My recollection is that we made no allow-
298 ance for pipe under street railway tracks. The total allowance made for steam railways and river crossings was $61,000. The amount $174,870 stated in the Harrison notes as covering property not used for water works purposes was not a part of the report of the board of appraisers. I have no such notes myself and no knowledge of what Mr. Harrison may have had in mind. As to the bridge carrying pipe for which we allowed $6,000, my notes show

steel, 26,331 pounds in place at 10c., masonry, 305 yards, $3,000, excavation for piers, $400 total, $5,030 rounded out to $6,000.

As to the question of title in these properties, or water rights, the case is the same as a horse which is worth just as much no matter what the title of the owner may be. We had it very clearly in mind that we were not to inquire into titles. We were finding value and the company would have to quiet title before receiving payment. I have investigated to ascertain whether there were other reservoir sites as good and as available as the Cheesman site. Have also read the reports of the Public Utilities Commission Engineers, of Mr. Hunter, and Mr. Phillips, and have come to the conclusion that the so-called Two Forks site is the only available site. It would cost there to reproduce a reservoir equal to Lake Cheesman about $5,100,000. Whether the attitude of the city of Denver toward the company should be taken into consideration in fixing rates is a legal question which I do not undertake to decide.

Recross-examination by Mr. Nye:

I will be pleased to furnish a copy of the table that I have bearing on depreciation. The salvage value of pipe in the event of the city constructing a new plant would be in 12 inch or larger sizes. I do not know what percentage that would represent. I do not remember the exact basis on which $100,000 was allowed for the business value of the property. It was a compromise value.

The 60 inch, 48 inch and 36 inch pipe lines would have a salvage value in connection with Marston Lake. I do not know what percentage of cost that would amount to. The Newburyport Water Co. case in which going value was allowed was a purchase case, in which purchase was practically compulsory by act of the legislature.

The board of appraisers made two reports on rates. One established the leaflet rate for the remainder of the contract period, the other informed the parties of the inability of the board to agree on what would be a fair schedule of rates for a period of 20 years. In discussing the cost of the reservoir at the Two Forks site I
299 was discussing a reservoir of sufficient capacity to yield the same quantity as Lake Cheesman. A reservoir to hold the same quantity as Lake Cheesman could probably be constructed at that point for very much less than the figure named, but not one to conserve that quantity.

If the city were developing that project it probably would pay to incorporate a power scheme with it for civic uses, but there would be no real profit in developing water power.

Redirect examination by Mr. Dorsey:

In the question of water rates for the remaining franchise period we were called upon to determine which would be the nearest to a fair rate, the leaflet rate or the leaflet rate less 10 per cent or 20 per cent. We found the leaflet rate to be nearest fair but my recollection is that we were unanimous in thinking that it did not give

quite as much return as the company was entitled to. It is clear that we did not consider that it gave more than a fair return.

Witness MINARD LAFEVER HOLMAN.

Direct examination by Mr. Dorsey:

I reside in St. Louis, Mo.; profession, consulting engineer; graduated with degree of Civil Engineer at Washington University 1874. Prior to graduation I received a practical training as mechanic in stone, wood and machine work, and had experience in railroad construction. Became connected with the Water Department of St. Louis in 1877, continuing until June, 1899, the last 12 years as Water Commissioner and member of Board of Public Improvements. Built new intake works, pumping stations, and I established the practice of letting contracts for pumping engine contruction on the basis of guarantee by the manufacturer. Also constructed the sedimentation system for the works and constructed two large conduits. Visited European cities to examine methods of filtration there in use. Also planned reconstruction and extension of the distribution system. The work done outside of the distribution system involved total expenditure of about $10,000,000. While connected with the St. Louis plant I acted as consulting engineer for a number of other cities. Was a member of the board that planned the new water works system for the city of Cincinnati. Advised Chief Engineer Hermany of Louisville in the construction and design of the works there. Also advised Mayor Cregier of Chicago in the same capacity.

Was employed with Mr. Hermany and Mr. Benzenberg on a commission to design a new water works system in Kansas
300 City, Mo., in a controversy between the city and the company. The plant designed was never built because that activity forced the matter into the courts and to a settlement. Advised the city of St. Joe, Mo., in similar matters. Had charge of the works in Omaha, Neb. when they were taken over by the city by purchase, operating them until the regular operating force was organized. Designed distribution system for City of Mexico. Retired as Water Commissioner of St. Louis because of poor health. Since entering upon the practice of consulting engineer my activities have been along the lines of hydraulic plants, water works, steam pumping plants, electrical plants, etc. Am member of the American Society of Civil Engineers, American Society of Mechanical Engineers; past president of both. Am an honorary member of the American Waterworks Association and I think the only active charter member living.

In 1907 was appointed member of the Board of Appraisers who valued the property of The Denver Union Water Company, being associated with Mr. Freeman, Mr. Harrison, Mr. Stearns and Mr. Hazen. Mayor Speer called on me at St. Louis October 21, 1907. I suggested Mr. Stearns to act with me as representative of the city and suggested Mr. Allen Hazen as chairman of the board. The

board arrived in Denver November 8, 1907, viewed the property and worked here until November 29th. We returned to Denver on Dec. 11 of that year and worked until Dec. 21. The board next met in New York from February 5th to February 14th, 1908, where the question of water rights was presented by counsel for both parties. The next meeting was in New York June 3rd to June 20th, 1908, the last meeting in New York March 3rd to 26th, 1909. In addition to the work on the board I worked in Denver from April 17th to May 5th, 1908, February 15th to 22nd, 1909, representing the board on the water rate schedule. Inventories of the property were submitted to us and we checked them so far as possible by examination of the property, the board being divided into committees representing both parties for the purpose of agreeing on such inventories. On those inventories we applied our judgment and unit prices, finally arrived at the value of the plant. The data which came into my possession as member of the board I returned to the City of Denver at the request of Mr. J. A. Burnett, President of the Board of Supervisors in June, 1909.

The meetings of the board were held in New York on account of the poor health of Mr. Harrison. He is now dead. Mr. Harrison was formerly Chief Engineer of The Denver Union Water Company and in charge of the construction of Cheesman Dam. The printed pamphlet which appears in the bill of complaint in this case is a printed copy of the report of the Board of Appraisers on
301 the valuation of the property. Other reports related to rates.

Total valuation found by the board $14,400,000; $10,354,-075 for the physical property, $100,000 for the business value relating mostly to the business under contracts with former municipalities now part of The City and County of Denver; $1,100,000 for the going concern value, which is the value found in a live plant over and above the value of a non-operating plant of similar physical characteristics. The water rights were valued at $2,845,925. There is included in the report a valuation by Victor R. Olmstead and William W. Watson, representing the City and the Water Company, as to the value of the real estate within the city, and a similar report by J. B. McNeil and Burton D. Sanborn as to the value of the real estate outside the city.

Said reports were used as a basis by the board in forming its judgment as to the value. J. B. Hunter, City Engineer, and W. F. Hawes of the water company, submitted a similar report as to the mains constituting the distribution system. The board accepted that report as a correct inventory of the pipe, etc., in the distribution system. The board also made a report on the valuation of the water works property owned by the City and County of Denver. The value assigned was $315,000. The personal property, that is, furniture, fixtures, material on hand, etc., also was valued by committees, Mr. C. F. Read and A. E. Hamilton representing the city and company respectively on the small materials, furniture, etc., and Mr. Stearns and Mr. Harrison representing the city and company on the heavier materials for pipe system construction, etc. The board was very frequently divided into committees, one member representing each

party, to expedite the work under consideration. The Chairman of the board also handled many matters by himself.

The board caused excavations to be made to permit it to examine the condition of the underground structures. Total value allowed for land and structures at Lake Cheesman was $1,955,000. Land $200,000, structures $1,500,000, interest-during-construction $255,000. The Cheesman reservoir site is ideal and the construction is the finest I ever have seen in hydraulic work. I do not know of another site available as well suited for a reservoir as Lake Cheesman. I should say that a reservoir at Two Forks of the same working depth as Lake Cheesman would cost four times as much. The board, at the time it made its valuation, inquired very carefully into the yield of the water shed above Lake Cheesman and arrived, I believe, at the conclusion that the reservoir would yield about 59 second feet flowing constantly throughout the year. The reservoir site is un-
302 usually clean, the lake surrounded by several thousand acres of land which is fenced in. It is desirable to so protect the lake.

The board assigned a value of $673,805 to Marston Lake; land $158,550, structures $454,000, interest-during-construction $61,255. When this valuation was made the sole source of supply to Marston Lake was from Bear Creek. Since then the Company has constructed new diverting works in Platte Canon and a 48-inch pipe line to Marston Lake, increasing its ability to deliver water to that reservoir, increasing the value and utility of the property and generally the value of the water rights of the company because of the ability to increase the use. Marston Lake is a desirable storage reservoir in close proximity to the city. The distribution system was valued at $3,870,165. The depreciation allowance on the reproduction cost of the pipe system, as I recollect it, was 10 per cent. Generally the amount of accrued depreciation on the property at the time of the valuation was determined from judgment of the various members who made their computations in their own way. Generally, reproduction cost is based largely on the judgment of the engineer making the estimate. We duplicate the property capable of duplication, and as to equipment no longer manufactured or impossible of duplication, we substitute equipment of similar capacity and capable of doing similar work.

Such substitution is an exceptional case. The first effort is always to reproduce the exact thing. In ordinary cases that is what is estimated upon. That was the method employed in Denver. The valuation found included all property used and useful in the water works system. There was an item of $174,870 listed in the report as property not used for water works purposes, consisting of lands practically, that were held as useful in connection with the future development of the system or because of their bearing on the water rights situation existing here. One item in that was the Rough and Ready Mill property, valued at $33,700. Though not actually used in supplying water, it is very necessary for the control and protection of water rights. I cannot say positively whether the ranches owned were acquired in connection with the acquisition of water rights. To

bring that appraisement down to date I would take the value then found, and additions to the plant, deduct depreciation and add appreciation in those items of property that have appreciated in value. I have so far as possible examined company accounts and inspected the additions to the property that are visible, as indicated by Exhibit Z, and find that the charges for such extensions are proper charges to the property and plant account.

303 I should consider in addition to those charges that an allowance of 20 per cent for overhead charges would be fair. On that basis, using $10,354,075 as the physical value in 1907, adding the amount expended $1,744,841 plus 20 per cent, or $2,093,809 to this value and deducting for depreciation on the old and new plant $900,000, giving the present value of the physical property as $11,547,884. In my judgment, water rights have increased in value about 25 per cent since 1907, making the present value of water rights $3,556,406; going concern value at 10% of the physical property would be $1,154,788; making the total value $16,259,078, or basing going concern value at 10% of physical property and water rights it would amount to $1,510,429, thus making the total value $16,614,719. I think the last method should be the method used.

From experience, I have come to use 10% of the tangible valuation as the basis for going concern value. I understand that is the law in Canada and that is about what precedent has established in this country, or from 10 to 12½ per cent. The fact that The Denver Union Water Co. at present has no franchise does not affect the going concern value of the plant; it has nothing to do with the franchise.

From my experience in operating water works, I should want to spend at least $400,000 a year for ordinary operation and maintenance of this property. That does not include any allowance for depreciation or for taxes. A fair allowance to be set aside, out of gross income, for depreciation on this property is $180,000 a year. The gross income on this property, to permit of handling its business and properly care for the plant, should be about 10 per cent of the gross value, or $1,600,000 on the present value. That statement is predicated upon my experience in operating similar plants.

The inventory known as Exhibit C, prepared by Messrs. Anderson and Metcalf, I believe covers the same property as was valued by the Board of Appraisers in 1907, with the additions and changes that have since occurred. The estimate of $180,000 annual depreciation allowance was based on the useful life of the plant as it now stands and on the theory of its continuing to operate to supply water to the city; it includes the ordinary depreciation allowance and an allowance for the unforeseen contingencies which always happen and have to be met by an expenditure of money. It does not in any way take into consideration the loss that would occur on the property were the city to construct its own plant.

Cross-examination by Mr. Patterson:

I consider my experience and knowledge to be my business capital.

304 I was employed by The Denver Union Water Company as consulting engineer in this case on May 6th of this year. I had never been employed by The Denver Union Water Company since my employment by the city until I became connected with this case, nor had I been in communication with The Denver Union Water Company from the time this report was submitted until about May of this year. Until that time my knowledge of the property, tangible and intangible, was acquired as consulting engineer of the City of Denver. I received a fee of more than $10,000 for my work in connection with the appraisal from the city. My position in the present matter is exactly that of an attorney who takes a case for a client and in the course of business he may have to take the case against that client. After a lapse of six years, I see no ethical question in the matter. In discussing the makeup of the Board of Appraisers with Mayor Speer, I suggested and advised the selection of Mr. Stearns to represent the city with me. After the board arrived in the city on November 8th, we went to inspect Lake Cheesman, remaining there from the 9th to the 11th. We took the oath of office November 12th, 1907. We remained here 21 days, working practically 18 hours a day.

We returned to Denver on December 11th and remained until December 21st, working about 18 hours a day. I returned to Denver April 17th, 1908, remaining here until May 5th, starting the work for the preparation of the 20-year schedule of rates. The work done in connection with the valuation of the physical property was not confined to the two first visits to Denver. I did a great deal of work in my own office in St. Louis; the actual work in Denver covered 33 days. I also saw considerable of the plant and city while here in connection with the rate schedule, to get familiar with matters in the event that the city should take over the plant and want my services while organizing. The first meeting in New York, from February 5th to February 14th, was devoted practically to a discussion of water rights. At the second meeting in New York, June 3rd to 20th, we continued the work of estimating the value of the plant and property. At that meeting we got into a deadlock on a number of questions, water rights being the most important. Between that meeting and the final meeting I did a great deal of work in my office, and corresponded with the other members of the board, particularly Mr. Stearns, and with Mayor Speer in connection with the matters pending. I wrote to Mr. Hazen submitting my views of the water yielding capacities of Lake Cheesman.

This is a carbon copy of that letter.

305 I do not recollect whether witnesses and counsel appeared before the board at the final meeting in New York March 3rd to 20th, 1909, but I think they did. I do not remember whether City Engineer Hunter was there or not. We completed our first report on March 20th of that year. Mr. Stearns assented to all parts

of the report except the water right valuation. The Board fixed the valuation at $2,845,925 for the water rights without determining the question of ownership. It was not for the board to decide ownership. The question of title had to be adjudicated as in any ordinary transaction, at the time of the transfer of the property. I personally recommended to Mayor Speer that the property be purchased at the valuation fixed. The board did not make any such recommendations.

I remember that C. S. Thomas, counsel for the city, attempted to make the point that the company had no title or a very imperfect title to a majority of the water rights, but my impression is that the lawyers subsequently agreed that the board was not to pass on titles anyway. My recommendation to the city to purchase was without an investigation of title. I might advise you to buy a house but would not expect you to consummate the purchase without investigating the title. The board attempted to determine the value of the individual water rights but finally agreed on the value of the rights as a whole. The testimony concerning water right values presented to the board was on an irrigation basis. My personal position was that the value should be determined on the basis of their availability for a city supply. My recollection is that each man made his own computations up to the total value. We did not at any time attempt to ascertain what the water company had paid for any of the water rights enumerated. (Objection overruled.) I went on the theory that it made no difference what the water rights had cost. (Objection overruled.) The language used in the list of water rights which accompanies the report is the language submitted by the company in explanation of the list of water rights and is not the language of the board.

I am not able to state whether the water rights of the Platte Canon ditch belonged to agricultural land in 1889. It is my understanding that until then they were used for irrigation purposes only and from then on were applied to domestic and all-around-year use by the water company, by appropriation and use. The water of the Rough and Ready Mill ditch, in addition to being used to protect the company's water rights, has been used in running a flour mill at Littleton. My understanding is that this power water can be taken for the higher domestic use upon proper compensation; owning it, the water company would not have to compensate itself for taking it. A contract with the High Line ditch gave the company carrying
306 rights in the ditch from the intake to Platte Canon reservoir. The appropriation of 2.50 second feet, as of December 20, 1870, I assume was by the erection of pumping station and the use of water through the pumps for city purposes.

I do not know how much of 24 second feet appropriated for the Mississippi Street galleries was underflow and how much direct from the stream. My impression is that it was all underflow. I understand that the Cherry Creek appropriation was also for underflow. The company is also allowed, in connection with the valuation of these galleries, for all expenditures for structures. The water right valuation was in addition to this. I would not allow a similar value in St. Louis for water diverted from the Missouri or Mississippi rivers.

The laws and situations are entirely different. In determining these values we did not take into consideration the money expended by the water company for the acquisition of any of this property. We estimated the cost of duplication less depreciation, then added the value of water rights as distinguished from property and labor.

We were not interested in whether the water company had paid a dollar for those rights or not. We presumed that its filings were made in accordance with the law. That applies also to the 34-inch and 40-inch conduits. It is my judgment that the rate of consumption in Denver during the peak-load hours exceeds a rate of 200,000,000 gallons per day; the conduits are flowing uniformly during 24 hours a day and put into the reservoirs the excess quantities of water that is taken out during the peak-load. The 278.26 second feet power appropriation for West Denver pumping station is about 2.73 times the maximum daily consumption in the city of Denver. This water is put through the water turbines at West Denver and used to drive the pumps. 278 feet a second is not much water for this purpose. That amount of water for power purposes is a mere bagatelle. I do not know whether the turbines are being used at the present time or not. At the time of the appraisal we had data showing the amount of water pumped by those turbines. They can be used in connection with or independently of the steam pumps. The water power is used as it comes in handy in the regular operation of the station.

The appropriation for Lake Cheesman, as I understand it, permits it to take all of the water that will flow into it at any season of the year to the extent of its capacity, subject to prior appropriations. We did estimate the value of stock owned by the water company in the Harriman Ditch Company, the Soda Lakes Reservoir and Mineral Water Company, or the Bergen Ditch Company. Marston
307 Lake, with a capacity of 6,449,686,848 gallons, was supplied by the rights of the water company through the Harriman Ditch Company, Soda Lakes Reservoir and Mineral Water Company and Bergen Ditch and Reservoir Company. The Harriman Ditch Company has appropriations for the benefit of Marston Lake and 18 other reservoirs and supplies them according to its ability to obtain water from Bear Creek. The available quantity of water obtained through this right, the Soda Lakes and the Bergen Ditch rights, for Marston Lake, was, up to the time of the appraisal, comparatively small, as I recollect it. I do not recollect the details of the reference to the water bearing lands in the list of real estate. A communication from Walter P. Miller, Secretary of The Denver Union Water Company, addressed to the Board, called attention to certain additional water rights that were omitted from the original list supplied to the Board. The valuation reached by the Board was based upon the availability of the water supply under the rights for supplying the water works of The Denver Union Water Company. I can not now give you the detail of the methods used by me in arriving at my figures.

The third schedule in the report of the board of appraisers is the list and valuation of the lands outside of the city by J. B.

McNeil and Burton D. Sanborn. The board according to my notes agreed upon a valuation of $358,595. for the lands outside of the city. This value included surplus water rights for the ranch land. We did not use the valuations given by McNeil and Sanborn except as a preliminary step in making up our judgment as to value. McNeil and Sanborn did not value the lands for water works purposes. $358,595 was the value that we placed upon those lands for water works purposes including a value for surplus water for the ranches. We valued the water rights in the water rights list as water rights for municipal purposes and we valued in connection with this land the surplus water allowed to remain with the ranches. The water for municipal purposes was valued on the theory of being used 365 days in the year. Water for the lands on the theory of its being used probably 50 days in the year.

In my report to the finance committees of the Board of Aldermen and the Board of Supervisors of the City and County of Denver I state how the different items of value are distributed. The Phebe Strong Ranch containing 680 acres was valued with surplus water at $17,060. McNeil and Sanborn valued 480 acres at $5. per acre 74 acres at $10. per acre and 126 acres at $140 per acre. We allowed less for the whole ranch than was allowed by McNeal and Sanborn for 126 acres with water. The William Strong Ranch, 280
308 acres was valued by the board with surplus water at $16,125. McNeil and Sanborn valued 145 acres at $20,300; 135 acres at $1,350. Improvements at $500. Total $22,150.

The Becky Archer Ranch, 160 acres was valued by the board at $13,750. with surplus water. McNeil and Sanborn valued 130 acres at $18,200. 30 acres at $300. Improvements at $1,000. Total $19,500. The Frank Archer Ranch, 600 acres was valued by the board at $37,850. and by McNeil and Sanborn at over $51,000. The Harriman Ranch containing exclusive of the Harriman Reservoir, 812.8 acres was valued by McNeil and Sanborn at $69,078. and by the Board of Appraisers with surplus water rights and including the Harriman Reservoir at $40,300. A number of figures in my memorandum are identical with McNeil and Sanborn's figures.

This report of McNeil and Sanborn was used simply as a guide in making up our valuation. I think the water company has structures on all of the ranches (Erroneous computation by Senator Patterson as to acreage contained in the ranches. He takes total acreage and adds to it subdivisions of total under which valuation was made. He figures 303 acres in the right of way for Harriman Ditch Flume instead of 3.03). We valued the 782 acres at the Marston Lake Reservoir site at $156,400. That valuation is not out of proportion for reservoir purposes to other land in the vicinity. There are no other lands so well suited for reservoir purposes. We agreed on that sum because we believed it was worth that much for a reservoir site. Personally I took into account what it would cost to acquire that land under the law of eminent domain.

McNeil and Sanborn valued the Sullivan Reservoir Site at $1,000. We valued the site and the partly constructed reservoir and materials at $5,000. The Cherry Creek gallery lands contain 144.7 acres. I

am unable to state the length of the galleries. I don't recall the depth to which the galleries are sunk. We valued everything that inventories were presented for.

The right of way of the 40 inch conduit from Platte Canon contains 120 acres. I do not recall the length of the conduit. There is room for additional pipe on that right of way. I am unable to say whether Block 7 Weir Addition is used in connection with the water supply. I am unable to say what relation Plats 2, 7 and 8, Block 38, Eastern Capitol Hill Sub. had to the water system. I am unable to say what connection lots 11 and 12, Block 48, second filing Highland Park had had to *do* the water system. All of block nineteen, etc.

Cottage Hill containing 33 lots is the Cottage Hill tank prop-
309 erty. Partly used for a tank site and partly for additions. Those lots were valued at $15,850. I am unable to say whether lots 1, 2, 3, and the north 5 feet of lots 4 in Block 10, De Lanpe place are necessary. Lots 23-26 Block 50 University Park are the site of the University Park tank. I am not certain, but believe lot 19 Block 33, Witter's First Add. is part of the West Denver Pumping plant. The valuation placed on the 10.80 acres of the West Denver pump station was $43,200. And the valuation upon 5.39 acres of the tail race of the West Denver pump station was $10,780. 131.557 acres known as the Archer Lake Canal and Mississippi Street gallery lands were valued at $174,334.50. Lake Archer is used in connection with the hydraulic pumping plant at West Denver.

I think practically all of the 131 acres is occupied. How much is occupied by each class of structure I cannot say. As I recollect the tank has been removed from the Alameda tank site.

The Ashland Avenue Reservoir site contains 8.37 acres. Lots 1 to 11, Block 1, Re-Sub. of Lakeside is the Ashland Avenue Pump Station Site. Lots 7-20 block 5, and lots 28-40 block 6 Chamberlain's Capitol Hill Heights adioin Capitol Hill Reservoir. I take it from the language, they are not part of the reservoir. The residence of the superintendent and office and headquarters of the River Division are located on lots 25-44, block 3, Littleton Heights. It is quite necessary to furnish accommodations for the superintendent who must be available 24 hours a day the year around. The land occupied by and the structures of the Littleton Mill were valued at $28,700. This property is in connection with the Rough and Ready ditch for which we allowed an additional value of $5,000 for the water rights. All of the items to which attention has been called, whether used or unused, except such as have been sold, are included in my estimate of the present value of the plant.

My recollection is that the board did not attempt to verify the inventories or valuation of minor personal property which were turned into it. This inventory included furniture, tools, etc. at the ranches, at the Littleton headquarters, the operating office and elsewhere. The board itself placed the values on the pipe system, simply accepting the length of mains, etc. reported to it. Total mileage of distribution system was 397.001. The price per foot allowed on pipe was as follows: 2 inch, 20c, 3 inch 30c, 4 inch 55c, 6 inch 95c, 8 inch

$1.35, 10 inch $1,80, 12 inch $2.20, 14 inch $2.70, 15 inch $3.00, 18 inch $3.80, 16 inch $3.30, 20 inch $4.50, 24 inch $5.80, 30 inch $8.20, 36 inch $11.00 all in primary lines. The secondary and triplicate lines probably cost as much as the primary lines when
310 laid. The prices given were the prices per foot in the present condition of the mains. $35.00 per ton was the price allowed for the pipe new. Then we computed the cost of laying and added 15 per cent for contingencies and engineering. The $35 was the price allowed for the pipe strung along the ditch. The average market price of pipe in Denver at the time of the appraisal was $40.68 per ton. We allowed the 35 dollars because we thought that was the fair price for the period during which such works would be constructed. I did not consider it fair to use the temporarily fluctuating price. The depreciation rate that I used on the primary lines was 10 per cent. The triplicate lines we did not value at all. On the secondary lines my deduction for depreciation was $179,520. I am not familiar in detail with Mr. Metcalf's life tables of articles of that kind. I have seen quite a bunch of guesses of the useful life of property and have also made a few myself but I do not know of any cast iron rule for determining depreciation on a pipe system. That depends entirely on the nature of the soil. We have pipe in St. Louis still in use much older than any in Mr. Metcalf's estimate. There are all kinds of pipe for all kinds of pressure, new pipe of some kinds would now stand 115 pounds and old pipe of other kinds would stand more. There are several standards for water pipe adopted by different technical associations and prepared by manufacturers themselves. The figures that I gave per foot for different kinds of pipe were for the pipe laid in the ground. It does not included fire hydrants, valves, or pavements. The 2,640 feet of 24 inch wood main was estimated at $6,500. The 30 inch pipe line at $196,300. The 34 inch pipe line at $281,200. I cannot state the detail of the cost in Denver for the reason I have so often expressed that I sent all of the details and inventory to the City.

In determining the mileage of the distribution system, I did not include any part of the conduits within the city. There are nearly 10 miles of conduit within the city. Depreciation has been applied to the prices given. The total valuation on the distribution system including hydrants, valves and street paving was $3,602,735 exclusive of interest during construction. I stated before that I estimated 10 per cent depreciation on the primary lines, more for the secondary lines and no allowance at all for the triplicate lines. I took into consideration the life of the several pipe lines in estimating the depreciation and concluded after examining the soil and with a knowledge of climatic conditions that 10 per cent was right for the primary lines. The highest depreciation allowed was 100 per cent on the triplicate lines. We couldn't do any better than that. As I said before I allowed $179,520 for depreciation on the secondary lines, of which
311 there were about 21.9 miles. I did not estimate that the way the board did but we agreed so closely on the totals that I accepted the board's estimate. I have been a member of the American Society of Civil Engineers since 1888. I would rather lean

to my judgment in determining depreciation than to the judgment of a committee reporting life tables to the society.

80 years was my estimate of the useful life of the entire pipe system in Denver. That is a matter that is up to the judgment of the engineers engaged in the particular appraisal. When a man has had considerably longer practical experience in pipe than any one of the gentlemen reporting life tables to the society he is entitled to his own judgment. I cannot say just how many openings I made in Denver streets to ascertain the condition of the pipe. I would rather take my judgment based on the openings that I have made than estimates on the subject by the gentlemen who submitted these tables. They are trying to arrive at some general rule for the general guidance of young engineers coming up. My judgment in this case was based upon my examinations in this case, I know the climate, I know the condition of the ground and those things that go to effect the life of pipe. And I know the pipe business. Deterioration usually is caused by electrolytic action on the outside and tuberculation on the inside. Electrolytic action may be caused by the pipe becoming a primary battery in itself due to soil conditions or may be caused by a secondary current produced by some other cause, such as street railway systems. The ground here is so dry that you do not get the moisture necessary to set up electrolytic action. When I was here in 1907 I looked that point up especially. There are approximately 89.43 miles of paved and surfaced streets underlaid by mains of the water company.

The total allowance for paving over mains was $204,200. This allowance was made as part of the reproduction cost without reference to whether the pavements were down when the mains were laid or not. There are 605 fire hydrants owned by the city of Denver according to my memorandum at the time of the appraisal, and 2,687 owned by the water company. The hydrants owned by the water company were valued at $51 each and the connections at $43 each. Making a total of $94 for the hydrants connected with the system. This amount is with depreciation deducted. The allowance of $43 for hydrant connections was based upon examination made in 1907, to determine the average cost. I estimated the pipe system in an entirely different way from the estimate of the board, but agreed as to the total. The pipe in the secondary lines was
312 just as good as in the primary lines, the additional depreciation was charged because we believed that there were two pipes in some streets where one was sufficient.

I estimated the interest during construction on the principle of the loss on the money necessary to cover the cost of construction while the money was tied up in the works. The allowance of interest during construction on Lake Cheesman was $255,000. That was an amount agreed upon by the board. I presume each member had his own theory upon which he computed it. Where we agreed very closely on totals we did not discuss the theory involved. The total allowance for interest during construction on the distribution system was $247,430. The board agreed on that total. Lehow Lake is a small reservoir in Platte Canon just below the filter beds. It is con-

nected with the water system, overlying the cribs of the 30 inch conduit and the water from it percolates through those cribs. The total valuation placed on Lake Cheesman by the board was $1,955,000. $200,000 for land, $1,500,000 for structures, and $255,000 interest during construction. I am unable to say how much of that land was conveyed to the water company by special act of congress.

I think my valuation on that land was higher than $200,000. Mr. Stearns and I averaged $200,000 as near as I can recollect. I did not take into consideration what the company paid for that land. They might have discovered diamonds up there for all that I cared. It was not a question of what it cost with me, if they were fortunate enough to get it for nothing that was their concern. It did not make a bit of difference to us what was paid for it. We were here to appraise the plant, not to examine the water company's records. I do not know that the company paid more than $1.25 per acre for any of that land and I do not care. I know they settled some mining claims but I paid no attention to that. I do not know what the contract price was for the dam. I depended upon my judgment as to what the value of that land was in connection with the water works system. In addition to the dam there is at Lake Cheesman the tunnels, spillway, headgates, the usual paraphernalia of valves and gates and a small electric plant. My recollection is that the value on the electric plant was about $5,000. At the time of the appraisal I estimated all these matters.

The detail of those estimates is not in my possession now, I sent it all to the city. There are also the houses, office, etc. My recollection is that the interest during construction allowance on Lake Cheesman was principally on the $1,500,000 on the structures. The interest was allowed on our estimate of the cost of reproducing the hypothetical plant which we computed and depreciated to
313 find the present value of the present structures. The interest allowance was made without regard to the original cost. I want to be perfectly plain about it. It was computed on the theory of compensating for loss of interest on the money invested while the dam was being constructed. I do not recollect what the interest rate was at that time.

We estimated the value of the structures at Marston Lake at $454,000 lands at $158,550. Interest during construction $61,255. Total $673,805. That work is practically all earth work. Among the items were, 650,000 yards of embankment at 25c. $162,500. Riprapping $80,000. I don't remember the yardage. Puddle trench $25,000. Spillway $3,000. Gate houses, tunnels, outlet work, etc., $106,300. Gate house superstructure, $6,000. Boat house $3,000. Windmill well and tank $1,500. Fence $500. Telephone Line $500. Buildings, 5,000, and the Johnson Ditch, $2,000. I haven't the detail of the remaining items.

Wood Pipe lines should be kept constantly filled with water. They can be kept full regardless of the quantity they are carrying.

Archer Lake at the time of the appraisal was used exclusively as a power proposition. The 30 inch conduit is about 24 years old. We

allowed considerably more than 10 per cent depreciation on that conduit. The net valuation was $196,300.

The net valuation on the 34 inch conduit was $281,200.

The estimated reproduction cost of the 30 inch line was $327,100. The depreciation 40 per cent. The estimated reproduction cost of the 34 inch line was $468,700, depreciation 40 per cent. The Mississippi Street conduit reproduction $32,200. Depreciation 50 per cent. That is about the rate we applied. Those are my personal memoranda and all I can find here. I do not know what the company paid for those lines. In all of these appraisals we have allowed overhead charges, during construction. My estimate of $400,000 a year for operating expenses does not include taxes. Contingencies and engineering allowed in the appraised valuation was 15 per cent.

In the estimate of $400,000 a year for operation I include that part of the time of the Chief engineer and the engineering department that is devoted to operation. In the appraisal we considered all of the special castings necessary in connection with the construction of the distribution system and estimated them new at $65 per ton. I cannot say whether the estimate on pipe length agreed to by Mr. Hunter the city engineer included the length of the specials or not. The distribution reservoirs are the Ashland Avenue, West Denver and Capitol Hill Reservoirs. The valuation of which was $354,800. The Capitol Hill Reservoir was valued at $215,000.

314 I do not know whether it is located on land leased from the city or not. The pumping stations in the city were valued at $344,750. In valuing the distribution system we included 4,950 valves at $132,500. I do not know what the original cost was. The numbers are as follows, 2 inch 21, 3 inch 29, 4 inch 385, 6 inch 2,005, 8 inch 484, 10 inch 183, 12 inch 595, 14 inch 59, 15 inch 9, 16, inch 82, 18 inch 27, 20 inch 12, 24 inch 51, 30 inch 8. I think the cost of these is in document No. 46, which I transmitted to the city. Of the $1,200,000 allowed for business and going concern value, $100,000 was partly for the business of the company outside the Denver franchise that would be turned over to the city in the event that it purchased the plant. Part of it was the general business connection of the company. (The Master suggests that in as much as the item of $100,000 has been eliminated from the present value there is no need of further discussion of the $100,000.) Going concern value is based upon the fact that the undertaking is established with business and business connections. The various and different parts are in successful operation. It represents the difference in value of two similar plants, one of which has an established business the other has to bear the burden of establishing it. A concern may have a large going value though its gross earnings are such that it is losing money.

Going value includes the cost of the development of business. In the early days of all waterworks they have to spend both money and energy to get people away from their cisterns, wells and rain barrels. In my judgment the profits of the business cannot have been so large as to absorb the going value. In arriving at the present value of the plant I took the appraisers' value of the physical prop-

erty added thereto my estimate of the additions to the plant since then and deducted depreciation. I then added water rights and going concern value.

I started with $10,354,075 the amount fixed by the board as the value of the physical property. To which I added $2,093,809 my estimate of the additions to the plant since the appraisal, making the present day gross physical valuation of $12,447,884. From that I deduct $900,000 for depreciation giving as the present value of the physical property $11,547,884. The amount of the depreciation is my judgment of the depreciation that has occurred. (Detailed statement by witness of the items constituting the additions to the plant since the appraisal.)

The total book charges of the company for these additions was $1,774,841, to which I added 20 per cent for overhead charges. The detail of the book charges is shown by Exhibit Z. The item of $516,195.78 for distribution system I understand is all for new construction. $10,730.42 is for improvements to the Capitol
315 Hill works. $23,990 is for improvements at the Ashland Avenue works $22,676 is for miscellaneous work on the property of the S. P. C. & R. Co. $10,500 is for additional water rights acquired through the purchase of stock in the Soda Lakes Reservoir and Mineral Water Company. $15,489.18 is for new buildings at the Wynetka measuring station. $13,681.69 was for the interest acquired in the Mullen Ditch. $36,393 was for the extension of the 40 inch conduit to the Ashland Avenue Reservoir.

Discount and expenses on bonds sold to provide money for the construction $148,768.28. Then there is a credit against that of $39,770.90 for real estate sold. Then to the physical value found I added the water rights increased 25 per cent over the value found by the appraisers, making the present value of water rights $3,556,000. It is my estimate and judgment that $400,000 a year would be a fair allowance for the operation of this plant.

Cross-examination by Mr. Nye:

When I was engaged in 1908 on the sub committee on the question of water rates I represented the board of appraisers as a sub committee of one. Mr. Robinson represented the company in the presentation of data. No one represented the city unless I did. I spent in all about 30 days in that work.—All of the time in Denver. Mayor Speer was consulted during the progress of that work. I do not remember that Mayor Speer was out of the city at that time and that Mr. Burnett was acting mayor. I was in Denver on that work in 1908 from April 17 to May 5th and in 1909 from Feb. 15, to Feb. 22. After the February meeting Mr. Robinson and I went east together, going to New York by *by* way of St. Louis and Old Point Comfort. A report was submitted to the board of appraisers discussing the entire rate problem with a suggested schedule of rates in detail. The schedule was not adopted by the board, which finally reported that it could not agree upon a 20 year schedule. The board did agree on the adoption of the leaflet schedule for the balance of the franchise

period. 10 per cent going concern value was allowed on the property owned by the City of Denver which was then appraised by the board. My personal estimate on that property is as follows: Schedule, $266,025. Interest $18,275. Total $284,300. Going concern value 10 per cent, $28,430. Total $312,730. Agreed value placed at $315,000 by the board. Engineering contingencies, etc., was included in the $266,025. The value of the city's property was estimated on exactly the same basis as the company's property.

We did not take into consideration the cost to the company of the Lake Cheesman land. We did not consider that its use
316 in connection with a city water supply gave it its value. In my judgment the water rights have appreciated in value 25 per cent since the appraisal. The use of water has increased and in addition to that it is my judgment that the water rights themselves have increased fully 25 per cent. If they have not increased I am sorry for the city. In six and one-half years a property as desirable and as necessary in this part of the country must necessarily increase in value. I have not examined back of the appraisal to determine what the ratio of increase has been in the past. They will continue to increase in the future in a decreasing ratio until they reach their maximum value. Probably in 60 to 100 years. In my recent determination I took into consideration the same property as in 1908 less the property disposed of and plus additions. The appraisal in 1908 was for the purpose of purchase and sale. My recent appraisal was for the purpose of ascertaining the fair value of the property as a basis for determining the fair rate of return. The capacity of Marston Lake is approximately 1/5 of the capacity of Lake Cheesman.

The capacity of the reservoirs was not the element considered in valuation. It was the cost of construction less depreciation. The two situations are entirely dissimilar, and there is no basis of comparison. We accepted the sites as they were and duplicated the work on the particular sites without regard to whether the sites could be duplicated. In estimating the distribution system I estimated the fire hydrant leads separately.

The length of the hydrant leads was 64,488 feet for 2687 hydrants. I depreciated the hydrants 10 per cent. The difference in valuation per acre of the lands at Lake Cheesman and at Marston Lake was based upon the difference in location. In my present valuation I accepted and used the valuations made by the board.

Redirect examination by Mr. Dorsey:

I was designated by the city as an appraiser. The compensation of myself and Mr. Stearns was paid by the city. Mr. Harrison and Mr. Freeman were paid by the Company. The compensation of Mr. Hazen the 5th appraiser was shared by the city and the Company. I consider that I was acting more or less in a judicial capacity and not as an advocate for the city. None of the information that was conveyed to me at that time was confidential. (Objection overruled.) I expect to be compensated by the D. U. W. Co. for my time and con-

nection with this litigation. I do not regard myself as an advocate of the D. U. W. Co. I returned to the city all of the data that I collected and obtained as a member of the board of appraisers
317 on June 23, 1909. I have not had any of this data in my possession since it was returned to the city at that time.

The data returned to the city consisted of the inventory, arguments, affidavits, reports of Field, Fellows and Hinderlider, and all of the evidence that was presented to the board. It is due to the fact that I had returned this data to the city that I have been unable to answer some of the questions asked me on the Cross examination. I recommended that the city purchase the plant at the valuation $14,400,000. because I believed that that was the proper thing for the city to do. Personally I paid no attention to the claims of the water company that some of its water rights related back to 1870. But paid attention only to the total amount of water available for water works purposes which I determined on the record then available. (Objection overruled.) The Marston Lake and other reservoir sites were not valued by McNeil and Sanborn. Our values for the ranches were a little more than the dry land values given by McNeil and Sanborn and considerably less than the irrigated land values given by them because we valued the ranches with only surplus water rights.

It is good engineering practice in estimating work of that character to estimate the price of cast iron pipe on a basis of the average for a period of years. The price of iron pipe fluctuates considerably. The board assigned for 115,555 feet of secondary mains in the distribution system a valuation of $66,091. It is my method to determine the loss of interest on the average amount of the investment for the average period before the structure goes into use. I did not compute interest on the entire amount from the beginning to the end of the construction period. I do not pay attention, except as an element, to original cost in determining the reproduction cost for the reasons that works may have been built at a time of very high prices and the work may have been carefully conducted or not which cannot be determined. The difference is the distinction between cost and value. What we try to find out by the reproduction cost less depreciation method is what it would cost to reproduce the identical works at this time. Interest during construction is computed with respect to this theoretical plant. In my judgment the $900,000 deducted for depreciation is the total actual depreciation that has accrued since the former appraisal on both the old and new work. I stated as my opinion that the gross earnings of this plant should be $1,600,000.

In finding for the adoption of the leaflet schedule for the remainder of the franchise period we meant that the leaflet schedule more nearly approached an adequate return on the property than either of the other two proposed rates.
318 Lands adjoining Marston Lake aside from any value for reservoir purposes have a higher value than lands adjoining Lake Cheesman. It is also a fact that in the case of Marston Lake all except about 100 of the 782 acres are submerged while in the case of lake Cheesman only about 877 out of 8,400 are submerged. In

my estimate of $180,000 per year for depreciation, I included not only normal depreciation but also provisions for a contingent fund to meet unusual accidents etc. The items that I gave Senator Patterson as the expenditures on Marston Lake included everything except engineering and contingencies.

Recross-examination by Mr. Nye:

The board of appraisers in 1908 first determined the question of value and then with that as a basis took up the determination of the question of rates.

Witness ALLEN HAZEN.

Direct examination by Mr. Dorsey:

I reside at Dobb's Ferry, New York. Am a Civil Engineer. Obtained my training at the New Hampshire State College, Massachusetts Institute of Technology and at The Technical High School at Dresden, Germany. Have been engaged in the practice for 19 years, mostly in connection with public water supplies. Have made designs from which many million dollars' worth of water works structures have been built. Among them Springfield, Mass. Portland, Maine. Albany, Poughkeepsie, Yonkers, Peekskill, Nyack, N. Y. Toronto, Canada, Washington, D. C., Brisbane, Australia, and a good many others. Have been connected in an advisory capacity with plants in Boston, Mass. Hartford, Conn. New York City, Philadelphia, Harrisburg, Pittsburgh, Reading, Lancaster, Pa. Columbus, Ohio, Indianapolis, St. Louis, Minneapolis, San Francisco, Winnipeg, and Ottawa, Canada, Norfolk, W. Va., Baltimore, Charleston and Columbia, S. C. and many others. I have appraised water works at Portland and Augusta, Me. Gardner and Athol, Mass. Three works on Staten Island, N. Y. supplying what is now greater New York, Ithaca, Cortland, and Waverly, N. Y. and Des Moines, Ia. Racine, Wis. Newburyport, and Gloucester, Mass.

Am at present engaged in similar work on the property of the Spring Valley Water Company, San Francisco. Was chairman of the Board of Appraisers appointed in 1907 to value the works of the D. U. W. Co. (Statement of qualifications and experience of C. L. Harrison, another member of the board now deceased.) Four
319 members of the board, Mr. Freeman, Mr. Stearns, Mr. Harrison, and myself were connected with the planning of the works of the Panama Canal, having been appointed by the then President of the United States. The board of appraisers took up the question pertaining to the Denver works November 1907. The board met in Denver early in November 1907, spent some weeks going over all parts of the system, discussing its adequacy, efficiency, and all peculiarities of the system that would have a bearing upon its value, in examining plans and records of the company and collecting all possible information about it. Also made arrangements to have certain classes of property appraised by local men familiar with those items. In December the board met again in Denver continued the examination and took up the discussion of reproduction cost and

estimate of depreciation. Also received the reports of the local men assigned to appraise and report upon the extent and value of different items of property. In February 1908 the board met again in New York to take up the discussion of water rights. At this meeting evidence was presented on this phase of the matter. It was the desire of all parties at that time to have the appraisal completed within three months, but that could not be accomplished. There was another session in New York in June 1908 at which the value of water rights, the value of property and rates were discussed. It was the intention after that to finish the matter in Denver, both parties insisting that the last meeting should be held there. Mr. Harrison contracted caisson disease and his doctor would not permit him to come to Denver.

The meeting was postponed from time to time to see if he would not get well enough to come and finally the last meeting was held in New York in March 1909, and the matter determined as appears from the record. We had a very complete showing before us as to water rights, in the form of reports and affidavits and arguments by counsel. Several reports were submitted by Field, Fellows, and Hinderlider. All of the reports upon valuations made by local men are attached to the report on the value of the property, a copy of which was included in the bill of complaint in this case. The report was unanimous except as to water rights. The schedule of water rights in said report is a list of the rights claimed by the company.

It was not an agreed list. The list of city real estate was valued by Victor R. Olmstead representing the city and William W. Watson representing the company. Agreed to as to property and to value. List of real estate outside the city valued by J. B. McNeil representing the city and B. D. Sanborn representing the company, was agreed to as to property, and value of land for agricultural purposes.

320 The extent of the distribution pipe system owned by both the company and the city of Denver was agreed to by Mr. J. B. Hunter, City engineer and Mr. W. F. Hawes of the Water Company. The extent and value of personal property, furniture, fixtures, tools, etc. was agreed to by Mr. C. F. Read, representing the city and A. E. Hamilton representing the company. Messrs. Harrison and Stearns of the Board agreed to the extent and value of the material in the pipe yard. Mr. Harrison representing the company and Mr. Stearns the city. I think the board accepted their values.

The members of the board went over the entire plant from Lake Cheesman down and its investigations were such as to thoroughly familiarize it with the property and put it in possession of all facts necessary to enable it to determine its value. The value arrived at was $14,400,000 for the entire works, divided as follows: Physical plant, $10,354,075. Water rights, $2,845,925. Business and going concern value $1,200,000. The value of the physical structures was based upon the reproduction cost less the proper allowance for depreciation. So far as records were available we took into consideration original cost of the structures. This related particularly to Lake Cheesman and the Platte Canon structures owned by the S. P. C. & R. Co. which were of comparatively recent construction. It is im-

possible for me to state what weight each member of the board gave to the element of original cost. Each member reached his own conclusion and in all probability gave different weight to it. Agreements were reached on the totals.

The board asked for information as to original cost of structures other than the S. P. C. & R. Co. and got some schedules from the engineer's office, but it was impossible to determine from these the actual costs of particular structures, except in a few cases. That condition is not peculiar to the Denver works, but is very common in water works operations. The $10,354,075, included an allowance of 15 per cent for engineering and contingencies. 15 per cent is a reasonable allowance. Records of work as large, compiled since this valuation indicate a higher percentage, but this was accepted at the time by the board. The total value of the physical plant included also an allowance for interest during construction. Interest during construction is the estimated amount of interest lost on money used for construction from the time it is estimated it would be paid to the time when the plant is assumed to go into service and begin to earn a return. The different men had different methods of computing the interest but the total was finally agreed upon and distributed by the chairman among the different items in a way that most nearly represented the ideas of the different members. It is one of the
321 items of cost that must be reckoned on in the construction of works. $850,000 as interest during construction was the amount allowed by the board for the entire works. The board according to its best judgment deducted the depreciation that had accrued on each item of the property up to the time of the valuation. The lands within the city limits were taken at the valuations fixed by the two local appraisers.

As to the lands outside of the city the board took the report of McNeil and Sanborn as conclusive as to value for agricultural purposes and used that as evidence in forming judgment as to value for water works purposes. As to the Lake Archer lands we accepted the Olmstead-Watson valuation and the board valued the water rights separately. In valuing the reservoirs, such as Marston Lake and Platte Canon we took the land value for agricultural purposes into account in reaching a value for the purposes for which they were used. I do not know what the procedure of the commission may have been in those matters. I have my own judgment and took it on the basis of reproduction cost. Acquiring land for reservoirs is common and engineers who build reservoirs have experiences in the difficulties they meet and expenses incurred. The land to be used is ordinarily a specific piece, limited by topography and entirely different in its boundary lines from the lines of the property when divided among owners and it is necessary to partition the property to get what is wanted. My experience has been that if you take half a man's farm you pay as much for it as though you took it all and if you have to buy them out you pay more than the land would be appraised for, because if they are satisfied there is no object for them to sell and you must offer them inducements to make it an object. Ordinarily a reservoir site will cost

from 2 to 4 times the agricultural value of the land. Sometimes a reservoir site will have a special value very much greater than would be reached in that way, but such additional value would not be taken into account by the board in these proceedings. The Lake Cheesman site is a very excellent and unusual reservoir site.

It was the duty of the board to arrive at the total value of the property and not the value of the items. In the case of Lake Cheesman where the total value was much greater than the land and the structures, it is my judgment that that total value would have been the same regardless of whether the land and structures had been valued at more or less than they were. Ordinarily reproduction cost less depreciation is taken to mean the reproduction of the identical plant at the present time but that is not always carried to a strict conclusion at every point for that would result in some absurdities. It has to be applied along somewhat
322 broad lines and with reason. After ascertaining the reproduction cost less depreciation, we took into consideration the availability, reliability and efficiency of the works as a water supply in arriving at the values.

The term business value, used in connection with going concern, followed the word in our instructions which required us to value it. My recollection is that it included the unexpired portion of the franchise with the city and the unexpired portions of some other miner franchises and contracts, with several municipalities which have since become part of the city of Denver. The allowance for that value was $100,000. The allowance for going-concern value was $1,100,000. It represents the difference in value between this plant as it is and a plant identical with it as to physical structures but without the business or connections and not in operation. Going value is the same with or without a franchise. It has been called, cost of developing business, and that definition has a good deal of merit. I should not consider it altogether cost, although it is largely a cost item.

Members of the board investigated to ascertain the reliable yield from the water rights. It was one of the things taken into account in determining their value. There never was an agreement upon that question because there seemed to be no necessity for trying to reach one. The board made no determination as to whether or not certain of the water rights of the company related back to 1870 as claimed in the list furnished by Mr. Miller. Two questions as to rates were submitted for determination by the board. First, as to the rates to prevail for the remainder of the franchise period, whether it should be the leaflet schedule or that schedule less 10 or 20 per cent. Second, to establish a schedule of rates that would be fair and just for a period of 20 years. The board reported separately on each question. On the first proposition the board found that the leaflet schedule was the nearest approximation to a fair rate. On the second proposition the board was unable to agree on a schedule that in its judgment would be fair for 20 years. In making the rate investigation we used the valuation of $14,400,000 as the base to be considered with respect to what would be a fair return. We

deducted from the valuation of the company's property the item of $100,000 for business value. $175,000 for ranch and other properties not immediately necessary for water supply purposes and something like 25 or 30 thousand dollars for inventories, etc., in connection with the ranches. Then we added $315,000 being the appraised value of the works belonging to the city which it was proposed that the company should buy in carrying on its work. That all came out, omitting unimportant fractions, to the starting
323 point. I presume when we deducted the ranches and ranch property we deducted the income and expense that went with them.

(List of tangible property excluded in rating base, except the ranch inventories.) These amounts are the values which the board of appraisers put upon these several items. The rights of way for many of the main pipe lines through these ranches was not taken into account in this computation. But it should have been. There is advantage in the ownership of the ranches that would seem to make it well worth while for the company to own and operate them, but we did not consider that they were directly necessary in the waterworks business.

I have seen the property of the D. U. W. Co. on two occasions since that valuation but have not tried to go over it in a systematic way, as if I were valuing it again. Assuming that new work has been added to the plant as set forth in Exhibit Z, a fair allowance in addition for overhead expense on such work would be from 15 to 20 per cent. $14,400,000 represented the fair value of the plant at the time of the appraisal. To bring that appraisal down to date I should add the new construction and deduct depreciation and such items in the old appraisal as are not now there. If there was evidence of appreciation of items in the old appraisal I should add that appreciation. On that basis I estimate the present value of the property to be approximately $15,300,000. I estimate that a fair allowance for depreciation on the property today is $150,000 per annum. In 1907-8-9, the board of appraisers estimated the depreciation at $135,000 per annum. The estimate of $150,000 is for straight depreciation with no allowance for contingencies. It is the sum set aside to make good the loss from wear and tear from all causes other than those that are taken care of by ordinary maintenance, repairs, etc. It is my judgment that the ordinary normal operation and maintenance of the plant can be conducted for $350,000 a year at the present time, not including extra expenses for litigation and in connection with special troubles which might run anywhere from $20,000 to $100,000 a year. In looking over the accounts of the company I am satisfied that there are some accounts in the last few years that have not been charged into operation that really should have been, such as special litigation and matters of that kind. Of which, it has had an unusual amount in the last few years. It is my judgment that the allowance of $150,000 for depreciation is a fair allowance to meet the annual reduction in value that may reasonably be anticipated in the property.

If experience proved that greater depreciation had occur-ed after

a period of years, it would be necessary to raise the allowance. It is my theory that the depreciation allowance should be sufficient
324 to make good all loss in wear and tear of the structures to which it is applied. It is my judgment that should the City of Denver construct a competing water plant in the next five or seven years, the value of this property would be reduced to what might be called a salvage value at the time that the new plant gets its business. I believe a conservative estimate of that salvage value is from $5,000,000 to $6,000,000, and that the reduction in value of the present plant and property in that time would be from $9,000,000 to $10,000,000. In order to offset that loss accruing to the company by reason of its being obliged to continue in the business, it would be necessary to increase the rates fully $1,000,000 a year in addition to the normal depreciation allowed.

The water furnished by this system is excellent for the uses and purposes to which it is applied. I think the larger items of city property for which deduction was made in the rating base in the former appraisal have since been sold. The Harriman Ranch also has been sold. Were I eliminating from the present property for the purpose of a rating base those items regarding which there is any present question in my mind, the deduction would be something in the neighborhood of $150,000. If this deduction was made the earnings and expenses of the ranches should also be deducted from the income and expense account. So it would not make any practical difference whether this deduction was made or not. Marston Lake is a desirable and valuable reservoir, advantageously located and destined in the future to play a more important part than it has in the past, in the supply to the city, unless the city should build a new plant. The methods of purification used in connection with the water supply of Denver are approved and proper methods.

Cross-examination by Mr. Nye:

When acting as chairman of the board of appraisers I acted as a member of the board, having a view to the fair valuation of the property. Within certain limits I should have agreed with other members of the board if they had come together on a sum for value. After our inspection of the works the different members of the board except Mr. Harrison, were equally qualified to pass upon the values of the different parts of the plant. Mr. Harrison naturally because of having been chief engineer had information about it that it would be more difficult for anyone else to have.

We certainly respected Mr. Harrison's judgment as to matters about which he knew and told us, but when it came to matters of value of structures, I think every member of the board had his own idea. Defendants' Exhibits 4 and 5 were before the board but
325 were not used by the board as a basis for unit prices. They may have been used by members of the board and by Mr. Freeman but certainly not by the board. There were some differences of opinion as to unit prices. I used $35 a ton as a fair price for cast iron pipe, not because it was an average price over a period of years,

I think it is always well to consider averages but not well to always use them. I think a proper price at this time would be a little less than $35 a ton.

The tendency of the market for some time has been downward. If the estimate of value were to be revised from the bottom up at this time that price would be revised, also all other items. Some would be up and some would be down. It is my opinion that in a general way they would about balance. Bringing the former valuation down to date is an approximate procedure. In estimating the cost of pipe in the ground the different members applied their own prices based on their own experience in that work. I have with me a record of the prices that I used. I have not compared with defendants' Exhibit- 4 and 5. And do not know how they compare. Exhibit 3 seems to be an exact copy of page 7 in my note book for the estimated cost of reproduction of the pipe system. It was impossible to obtain accurately from the records of the company the original cost of different pieces of pipe laying in Denver. Exhibits 7 and 8 dealing with paving seem to be exact copies of pages 11 and 12 in my note book except for a typographical error of $4 in the last figure. Exhibits 7 and 8 contain the unit prices applied to the schedule of pavement over mains. It is my recollection that these were the figures used and agreed to. The board had practically agreed on the value of the physical plant within three or four months but did not finally agree on anything until they terminated their work late in March 1909. The board had before it the most complete showing in regard to water rights that I have ever seen in reference to a corresponding case. It is true that we did not accept the conclusions of Field, Fellows, and Hinderlider as set forth in their reports, but it is not true that their reports were rejected. They certainly were studied and given what the board considered careful consideration. It is true their conclusions were not adopted. The members of the board took into consideration the priorities of the company's water rights and the question of the all-year-round domestic use as distinguished from irrigation use in determining the water valuation.

There was no agreement on the question of all-year-round rights. Personally I considered the winter use a new appropriation initiated from the time that it began to be used. I based my value upon that theory. I know that the city disputed the claim of ownership
326 by the water company. The valuation placed on the lands at Lake Cheesman was $200,000 and on the structures $1,500,000.

I was aware that the lands cost less than $200,000. I remember that 7,600 acres were obtained from the government at $1.25 per acre. The board was of the unanimous opinion that the lands purchased from the government at $1.25 should be put in at that price plus the cost of fencing, acquiring, and carrying the property up to the date that the reservoir was put into use. There was no difference of opinion upon that point at all. The balance of the property, some hundreds of acres, had been acquired by the S. P. C. & R. Co. at a cost of $150,000. That cost Mr. Harrison told us he believed

was the cost of the land to those who had bought up the mining claims, the saw mill, and other property. And their carrying charges up to the time this work was undertaken. Of course, these costs go back of parties having anything to do with the D. U. W. Co. and we had no opportunity to audit that account. We had old maps showing mining claims across the site of the reservoir and we heard that these claims had been bought out at heavy cost. It was our understanding that these lands covered by the water in the reservoir, largely, if not entirely, had been bought by the company at an expense of approximately $150,000. This was one of the things that was presented to the board and considered. It was not controlling. Some of the members of the board believed that the site was much more valuable. All of the members of the board did not agree to the $200,000. The fact that the reservoir was used for supplying Denver with water was one of the elements of value, but there is another element quite as important. Someone went up there, discovered the site bought the ground, appropriated the water, built a dam, and got a water supply which in this locality is of very great value. Perhaps the value for other uses might not have been exactly the same but it would be large.

If the water company had been told in advance that its earnings were to be limited to cost of new works, then surely costs would govern, but the company was not so informed and as it is customary in American institutions for property to be rated at its worth, it seems to me that fair worth should govern and not original cost. I do not think that fair worth is created by the City of Denver and the use to which the reservoir is put. It is valuable for irrigation and other purposes beyond its cost. The cost of the structure was somewhat less than $1,500,000. The estimate of the board was the reproduction cost at that time and was somewhat more than the original cost.

327 The original cost was something like $1,150,000. Most of the increase was in the cost of labor, material also was higher. $255,000 was the amount allowed for interest during construction. I think all members of the board agreed on $100,000 for the business value. I should think there would be a difference in the ratio of going concern value to physical value in the case of a company that must educate people to use its commodity and the case of a company furnishing a commodity that everyone must have. I do not think that the fact that the company's franchise was about to expire has anything to do with going value. I know of no reason why going value should be different in a rate case than in a purchase case.

I first determined the value for purchase, then applied certain deductions and additions in determining the value for rating. I made that calculation personally and gave it to the other members. I think it was accepted but there was no agreement on it. Except for the changes stated the value was the same for purchase as for rating. My judgment was that the going value was approximately equal to one year's gross income. My method was really a consideration of the lack of income which a similar new plant would experience from the physical and business impossibility of starting business at its full

capacity. The item of $150,000. to which I called attention should be eliminated from the present rating case if the revenue and expenses of the ranches be also eliminated. Though it could be figured either way without any difference as I see it in the result. The company could sell the ranches retaining rights of away for pipe lines. The company could not afford to sell them with any claim on the water whatever. Owning them and using the surplus water in not very dry years, the company can operate them as wet ranches but could only sell them as dry ranches. I also included in that list for elimination the Littleton Mill Property. I did not include Lake Archer. Lake Archer and the power there is convenient to the operation of the plant. It is not essential. At the time of our inspection six years ago, that power was used all the time when there was water enough to operate it. I cannot say how it is now.

I think going value is an element of real value. It is also to a large extent an element of cost. And as an item of cost it seems to me that it is a part of the capital, that must fairly be taken into account in discussing fair rates. It is an element that grows out of the real conditions of the business and adds both to the value of the property and to the rates that are fair.

Going value is an element of value that stays with the plant all the time and you cannot write it off because of any earning
328 power that the plant may have possessed at any time during its history. In bringing my estimate of value down to date I excluded from the figures given in Exhibit Z. the item of discount on bonds. I did not make the same allowance for overhead expenses in addition to the charges shown in Exhibit Z. that I would have made had the company not been actively operating under organized management. The rates might be increased to offset the loss that would be occasioned by the city building a new plant without raising them to the point where the charge for the service would exceed the value of the service to the consumer. The actual value of water service rendered is enormously greater than the rates charged. Rates could be established to amortize nine or ten million dollars in from 5 to 7 years and still be fair to consumers. I do not think it is true that the fair value of water service to consumers is the fair return upon the capital necessary to construct a new plant. Denver if necessary could well afford to pay the whole value of this plant for one year's service if it could not get water otherwise. (Objection to question to the effect that company's rights were obtained for benefit of consumers overruled on the understanding that benefit of consumers be understood to mean for the purpose of supplying water to the consumers.)

I distinguish between what is a fair rate for the service and the value of the service to the taker. A payment of that magnitude would not be a fair rate for the service, but when it comes to discussing the value of the service I believe absolutely that it is worth that. I am taking into consideration that the consumers must have water but I think they could find other means of getting it if the supply was shut off. I know that since this company was organized down to the year 1910 it operated under a franchise which expired in that

year. I am not advised that the company since 1910 has operated at a profit. I have seen some schedules tending to throw light on that feature. I think it is true that the company operated with the knowledge that its right to operate was limited. I did not take that into consideration. I made my determination of value on the assumption that the company had no right beyond that which grows out of existing conditions and the necessity of the city for service. (Objection to question as to whether depreciation has accrued by reason of city's threat to build a competing plant; overruled. Exception.)

I do not recognize that any such depreciation has accrued up to the present time. The threat of the city to build a competing plant undoubtedly has reduced the value for which the plant could be sold, but the inherent value today is just as great as it ever was. I should say that such special amortization would commence at the time
329 that the rates were increased to provide for it. In this case the company believed until about a year ago, that it had a valid contract with the city which protected it from that procedure, so that process if it was the company's duty to follow it, would have started perhaps a year ago instead of four years ago.

Redirect examination by Mr. Dorsey:

The price of $35 per ton allowed by the board for cast iron pipe resulted from a consideration of the fluctuation in the price of pipe. It is proper to take such fluctuations into account. It is my recollection that the paving schedules before the board were agreed to between the city and company as to quantities but not as to values. No depreciation was allowed on Cheesman Dam at the time of the appraisal. It is my impression that there would be no depreciation on Marston Lake and perhaps on some other structures. Whatever the situation is, is because the board had determined from investigations that no depreciation had occurred. The property owned by the city valued at $315,000 was included in the rating base for the rates to be provided for the next 20 years.

I do not think that it was added when we were considering the rates for the balance of the franchise period. The company was paying the city rent for these pipes, so for that purpose it entered into the operating account. In discussing certain property that was essential or not essential, I construed essential as meaning absolutely necessary in the sense that it was indispensable under any circumstances. There is considerable difference between things which are reasonably necessary and essential for the purpose to which they are applied and things that are absolutely indispensable. Lake Archer is quite useful in connection with the property, without it the turbines at West Denver could not be operated. They are operated at present as a part of the plant. It is my idea that the net returns from the element of going concern value would be the same in a rate case whether you added that element to capital value or allowed a higher rate of return to compensate for its exclusion.

A rating base may be arrived at that does not represent the actual value of the property, but if the base was lower than the value of the property, then the rate of return would have to be higher in per cent

than if the actual value of the property was used as the base. Examples of that occur in England where under the older custom utilities were permitted to earn ten per cent on their cost which usually represented a lower but still fair rate upon their actual values. Theoretically the result was the same. Unusual conditions are met in Denver in supplying the city and its inhabitants with water. The
330 rainfall is very small, the amount of the water supply is limited. What is available has been largely appropriated under the laws which are different from other states so that it is very difficult to find a body of water suitable for a municipality that has not been appropriated or where the appropriations can be bought at reasonable prices and where the amount available is all in one place, or in a few places, so it can be handled economically and efficiently for a city water supply. It also is necessary to provide large storage reservoirs. The city is spread out so that the expense of the distribution system is great. And an immense amount of water is wasted in Denver. The consumption per capita is very much greater than it ought to be. In creating a water works system a very large initial investment must be made before any use of water begins. The item of discount on bonds is not included at all in my estimate of the present value of the plant. That expense however should be taken care of in the rates provided.

I assumed that that expense would go in with bond interest. It would necessitate an increased rate of return. The allowance of $350,000 a year for operation contains no provision for such expenses. I included in the loss of 9 or 10 million dollars that would accrue when the city put into operation its own plant whatever loss would be occasioned by the difference in the value of the water rights for domestic purposes over their value for irrigation rights, so far as such a difference may exist. It is very likely that the item of water rights could be disposed of for the full value for which they are put in this schedule. Perhaps they would go for more. But I cannot say at this time. The salvage would be in Lake Cheesman, Marston Lake, and the Platte Canon rights. There would be some relatively small salvage on the plant here and there.

I doubt that the company would show any profit on its business since 1910 after all the items that I think should be charged against income are marked off. My idea of profit is this, operating expenses, taxes, and depreciation should be marked off and also a sum equal to the interest charge at which the company can borrow on a sum representing the whole value of its property, after that any earnings would be profit, and in my judgment a reasonable profit is necessary and legitimate. Existing rates would have to be nearly doubled to amortize the loss of nine or ten million dollars which will occur from the city building its own plant.

Recross-examination by Mr. Nye:

The allowance for paving on primary lines was $175,600, on secondary lines, $28,600. In my valuation I treated the system as

though it were owned by one company paying no attention to
331 the fact that part of it was owned by the S. P. C. & R. Co. I did not consider that the accumulation of silt that had occurred in Cheesman and Marston Lakes was sufficient to constitute depreciation. I do not know whether the steam equipment at West Denver Pump station is of sufficient capacity to handle all of the work of that station. The use of meters would tend largely to stop the waste of water in Denver. It was my understanding that the company's contention in the case recently decided by the Supreme Court of the United States, was that the city should either buy its plant or grant it a new franchise.

Redirect examination by Mr. Dorsey:

The board allowed a valuation for pavement over mains, because we thought it was an essential part of the cost of reproduction and as such belonged in the estimate. The accumulation of silt in Cheesman and Marston Lake would be very slow. It is much cheaper to run the pumps at West Denver by water power than by steam. During the investigation by the board of appraisal the question of installing meters was urged upon the city and the company. We were instructed that the city was unalterably opposed to the use of meters and would not consent to a change to a schedule looking to their more general introduction. I knew at the time that the franchise gave the company the right to install meters under certain conditions.

Witness ABNER T. YOUNG.

Direct examination by Mr. Dorsey:

Am a civil engineer. At present General Manager of the San Louis Central R. R. for six years I was right of way agent for the U. P. Railroad and purchased rights of way along the entire system including some lands for terminals in Denver, Sterling, Salina, Topeka, Central City, Stromsburg, and many other cities and towns along the road. Appraised part of the terminal lands in Kansas City, Kansas, and Omaha, Nebr. As general manager of the Cheyenne Electric I acquired rights of way in Cheyenne and as Chief Engineer of the Colorado and Kansas R. R. I had charge of acquiring rights of way and terminals in Pueblo. I have charge of acquiring rights of way for the company with which I am now connected. Have recently had occasion to consider certain lands of the D. U. W. Co. with respect to their value for rights of way.

Exhibit A. 4. shows these lands extending from the Mississippi Street galleries on the south in a generally northerly direction
332 to the South Platte river where the tail race from the West Denver Station runs into the river. Archer canal and one of the conduits runs through this land. The conduit from the Mississippi Street galleries to the pumping station and the canal from West Virginia Avenue to the pumping station. Part of the land is occupied by lake Archer, indicated by the large green plat on Exhibit A 4. According to my information all of the lands colored on

the map whether yellow or red are the property of the D. U. W. Co. The land colored in yellow shows the continuous right of way through the lands owned by the company, including with it the land occupied by Lake Archer which would be particularly valuable for railroad shops and grounds. Discussion of objection to interrogation of witness as to reproduction cost of right of way. Overruled. Exception. My estimate of the cost of reproducing that continuous strip of land under present circumstances is $664,586. In determining that reproduction cost I took the separate tracts of land as the acreage was given me, arrived at the basis of valuation from the valuation of adjoining property plus what I considered a fair allowance for damage to adjoining property. There is no hard and fast rule for the settlement of right of way values. It is a matter largely of doing the best that one can with each owner. In running through a subdivided tract where there are a number of small owners the cost is much heavier than in a similar unsubdivided tract with one owner.

(Detailed statement by witness of methods used in arriving at his estimate of reproduction cost. The record itself is about as concise as it is possible to make the statement and convey intelligently an idea of the process.) In allowing damages to adjoining lands I assumed that the amount allowed would be the amount that would have to be paid in addition to the price of the land actually occupied, because of that damage which was bound to result from the use of land for rights of way. In my judgment it would cost fully as much to reproduce that right of way for water works purposes as for a railroad if not more, because the disadvantage of having the property cut up or cut off from the outside world would be there without any of the benefit derived from increasing the value of some land for trackage purposes.

The land at present occupied by Lake Archer would be particularly valuable for a railroad yard. I think the price stated would cover the cost — such right of way and consequently is its value. I have made no allowance in it for any buildings that might have to be destroyed and moved and I think I have been conservative rather than otherwise. I really believe that a million dollars would be a fair price for that strip as a railroad right of way. Giving
333 access as it does within one and three-quarter miles of the Union Depot and extending well to the outskirts of town and in view of the fact that it could be had without long legal trouble and the both or delay of condemnation proceedings. I estimated the actual cost of the land at $520,836 to which I added overhead and contingencies amounting to $78,125, and interest $15,625, being six per cent on one-half of the purchase price and overhead for one year.

Cross-examination by Mr. Nye:

I have not undertaken to identify or value the lands marked in red on Exhibit A 4. I estimated damages to the lands shown in red in the South East quarter of Sec. 9, adjoining the lands shown in yellow. Also in the N. E. ¼ of Sec. 16 and in the N. W. ¼ of Sec. 16. I also allowed damages there to lands that do not belong to the D. U. W. Co. but which would be damaged by reason of being cut

through at an angle. I did not estimate damages to the lands owned by the D. U. W. Co. in Sec. 15 lying east of the right of way because they would not be isolated and could be subdivided and used to advantage in that way. I allowed practically no damages to the land of the D. U. W. Co. in the S. E. ¼ of Sec. 16 west of the right of way between West Virginia and W. Exposition Ave. The right of way goes through there practically in a straight line and does not effect the balance of the ground. I estimated damages of 25 per cent to the land of the D. U. W. Co. in the N. W. ¼ of Sec. 22, south of Mississippi Street, basing its value as gravel land and not as filtration galleries to which use the land is now put. I took the land as though there was no present right of way there and if there was not there would be no filtration galleries. The line of the right of way is at present partly occupied by the conduit and partly by the Archer Canal. Part of the right of way is not now occupied by any structure. I am not prepared to answer whether a right of way of 100 feet is necessary for a conduit, except to say in a general way that I would consider it advisable in buying a right of way for a conduit to take at least 100 feet. I think the width of the Archer canal where it occupies the right of way is fully 50 feet. The water carried by the canal I assume could be carried through a pipe or covered flume, that is simply a question of expense.

I think this particular right of way would be especially valuable for railroad purposes, or for this company either. Were I acquiring a right of way into the city I would consider that a very fair entry. The maximum curvature, except at the pump station is 10 degrees. While at the pump station it would take a 16 degree curve which is not unusual in cities. I think a railroad company would be
334 getting that right of way very reasonably at a million dollars. I don't think the value of that right of way will ever grow less. The fact that the D. U. W. Co. owns the land indicated in red along the right of way does not increase the value of the right of way. The only ground that I consider valuable for railroad purposes outside of the right of way is that now occupied by Lake Archer.

I valued the portion of the right of way extending south from Mississippi Ave. at $1,500 per acre as gravel land. And the land just south of Exposition Ave. on the west of the right of way at $1,400 and $1,500 per acre.

Cross-examination by Mr. Patterson:

The infiltration galleries are between the west bank of the Platte River and the right of way. Part of the land north of the infiltration galleries could be used very nicely for truck gardens but I would say that most of it is more valuable for gravel than for truck gardens. I should say that for a third of the distance the land would be exceptionally good for truck garden. For a considerable portion of the distance the conduit is not in the right of way selected for railroad purposes. The Archer Canal commences about at the point where the channel of the river is marked as crossing the right of way. And from that point to West 4th avenue the conduit is not on the right

of way at all but at the edge of it for some distance. I paid no attention to the depth at which the conduit is laid. I was valuing the property. Streets and alleys could be laid out across the part where the conduit is. When you come to the ditch that is a different matter. The right of way to the north and west of the pumping station is simply the tail race.

If I were buying that right of way I would buy it just as cheaply as I could. But I am basing the price on what experience has led me to believe I would have to pay. The right of way for the conduit where it adjoins Lake Archer is about 30 feet and with the embankment of Lake Archer about 20 feet. I am not prepared to state whether that is sufficiently wide for a conduit right of way. They get along with it now and I would not consider it advisable to get an additional 50 feet. I am not prepared to answer what width is necessary from a water company view point. For a railroad the 100 feet is necessary.

Redirect examination by Mr. Dorsey:

If I had assumed damages on the theory of the ground south of Mississippi St. being used for an infiltration gallery the allowance would have been greater. I marked out the lines shown in yellow on the map to indicate where the railroad right of way would be.
The coloring was done by a draughtsman for the water
335 company. If the right of way had followed the line of the conduit, it would not have affected the cost. I simply swung the right of way as far east as possible from Alameda Avenue south to get a better river crossing.

North of Alameda Avenue the open ditch is on the right of way. I don't know anything about the width requirements of a pipe line right of way but I should consider it good business judgment in buying a right of way to buy for the future. The right of way is not in the river bed any part of the way.

Recross-examination by Mr. Nye:

In valuing the right of way I did not consider the water company in the matter at all. I simply considered the cost of acquiring such a right of way and yard room from land owners. I might equally as well have considered a strip paralleling this strip owned by other parties. I simply considered this land as though in the same condition and applied to the same uses as adjoining land. This land will be worth as much for right of way purposes, if abandoned by the water company when the time comes that another railroad wants entrance into the city and that time will surely come. From an operating view point I should say that it would be a disadvantage to a railroad company to have that conduit on the track or near. From Exposition Ave. to the West Denver pump station there would be no material interference with the right of way by reason of the conduit. I considered that the right of way would damage the lands of the D. U. W. Co. at the Pump Station site between west Alameda and W. Bayaud avenues and also South of west Alameda

and north of the river. $10,000 approximately would cover the damage to the land of the D. U. W. Co. except at the pump station, where I estimated the damage at $31,400.

Redirect-examination by Mr. Dorsey:

The total length of the right of way is approximately 4 miles and it contains 78.05 acres. I very much doubt if another right of way into the city from that direction of the same length and giving the same advantages could be obtained for that sum of money. Most any other right of way would run through some built up districts where it would cost from $10,000 to $15,000 a mile for buildings destroyed. Also there are very few street crossings affecting this right of way which is a great advantage.

336 Witness, ARTHUR D. WALL.

Direct examination by Mr. Dorsey:

Have been engaged in the real estate business in Denver for 26 years. Principal activities in land and irrigation matters. Am familiar with values of lands, irrigated and non irrigated in the vicinity of Denver. Have recently investigated the value of certain lands said to belong to the D. U. W. Co. and listed in Exhibit C. of these proceedings, beginning at page 111, the items being designated by numbers. My investigation was confined to the lands outside the city of Denver, excluding the lands at Lake Cheesman.

The valuations placed upon the lands by me were for use for farm and ranch purposes. They are worth much more for the use to which they are dedicated in many instances than for the purpose for which I valued them. Item No. 2, page 111, 152.624 acres was valued for grazing land at $765. Item No. 3, page 111, 306.65 acres generally pasture land with small areas suitable for farming are valued at $3,065. Item No. 4, page 111, consisting of two parcels, 7.768 acres valued at $115, and 85.25 acres at $8,525 or $100 per acre, including the water right of 1 cubic foot per second in the High Line Ditch. This valuation was made without the regard for the fact that this land is occupied by the Platte Canon Reservoir. Item No. 5, page 111 two parcels 3.22 acres valued at $100 per acre from which was deducted the value of water right necessary. 11.06 acres valued at $340. All of these lands under the ditches and reservoirs of the D. U. W. Co. are provided with water rights which are subject to use for domestic purposes when needed, only surplus waters being applied to the land. The irrigable lands therefor were appraised as with water rights attached. A deduction of $60. per acre has been made to cover the difference between a first class water right and a surplus water right. Item No. 6, page 111, 22.99 acres 16 acres valued at $100 per acre and 6.99 acres at $20 per acre. Net valuation after deducting for water rights $780. Item No. 7, 19.95 acres valued at $300. 10.03 acres at $155. Item No. 8, 13.08 acres practically all submerged by Lehow Lake valued at $520. Net.

In my judgment these various prices are the fair market values of the lands for agricultural and grazing purposes without regard to the uses to which they are now put by the water company. Item No. 9. Phebe Strong ranch containing 680 acres, 126 acres at $18,900. 554 acres of pasture land $5,540. Total $24,440. Making deduction of $7560 for the difference between a first class and a surplus water right on 126 acres leaves $16,880. plus $1200 for farm building making the total net value of the ranch $18,080.

337 Item No. 10, page 111. William Strong Ranch 280 acres. 145 acres of irrigated land valued at $21,750. 75 acres of pasture land $750. 60 acres of bottom land $1200. Total $23,700. Deducting $8700 for the difference between a first class and a surplus water right on 145 acres leaves a net value of $15,000 plus $800 for farm buildings making a total net value of $15,800.

Item 11 Page 111. The Becky Archer Ranch, 160 acres. 130 acres of irrigated land $19,500. 20 acres of pasture land $200. 10 acres of bottom land $200. total $19,900. Deducting $7800 for the difference between a first class and a surplus water right for 130 acres leaves a net value of $12,100. plus $1000 for farm buildings making total net value of $13,000. Item No. 12 Frank Archer Ranch 587.60 acres 320 acres of irrigated land $48,000. 225 acres of pasture land $2250. 42.6 acres bottom land $850. Total valuation $51,100.

Deducting $19,200. for the difference between a first class and a surplus water right leaves a net value of $31,900 plus farm buildings, $6,000. making total net value $37,900. In our opinion the farm buildings cost two or three times that amount but we questioned if a place of that size would as a farm proposition stand an investment of over $6000 for farm buildings so we placed that value on them. Item No. 13, page 112, Mountain Reservoir site 810 acres, valued as pasturage at $6,075. Did not take into consideration its availability or desirability as a reservoir site. Item No. 14, page 112, dam and headgate Harriman Ditch at Morrison, 11.84 acres valued at $1,000. Bear creek runs through the land, the Colo. and Southern R. R. along its northern boundary. The adjoining land is platted into lots and blocks. Parcel No. 31, Jefferson, a 20 foot strip along the Harriman Ditch valued at $50. Item 15, page 112, Harriman Reservoir, 130 acres valued at $16,250, as irrigated land including water rights; deducting $7800 for the difference between first class water rights and surplus water rights leaves a net value of the lands of $8450.

Item No. 16, page 112, Marston Lake Flume 7.58 acres a 50 foot strip through 3 choice farms valued at $1137. Item No. 17, page 112. Marston Lake reservoir lands, 840.224 acres 740 acres valued as irrigated land, $111,000. 67 acres $3350. 33 acres at $330. Total valuation $114,680, deducting $44,400. as the difference between a first class and a surplus water right leaves a net value of $70,280. plus $1500 for farm buildings makes a total net valuation of $71,780. There are other buildings on the grounds that are used for water works purposes, which we did

not value at all. Item No. 19, page 112 Sullivan Reservoir site. 80 acres valued at $2000.

338 This land can be irrigated from the Castlewood dam project which fact was taken into consideration. We allowed no value for the partly constructed reservoir. Item No. 20 page 113, 147.04 acres. 20 acres with a water right from the High Line Canal valued at $2000. 40 acres of bottom land, $2000. 87.04 acres creek bed land, $870. 3 brick houses in poor repair $1500.

Deducting $500. for the value of the water right leaves a net value of $5870. Item No. 34, page 114, and page 115. 40 inch conduit lands, 20 acre tract Woodbury land valued at $1500. (Detail of valuation by tracts.)

Total valuation for right of way, fee title, $17,118.75. Valuation of separate parcels were made according to the value of adjoining lands. Items No. 35 page 115. 6th conduit lands 9.926 acres $2,930.40. Item 36, page 115, 7th conduit lands, aggregating 17.5 acres total valuation, $1,978.85. Item 34, 35, 36, are lands owned in fee by the D. U. W. Co. for rights of way for its several conduits. Item No. 37, page 115, describes 58 miles of conduit rights of way for which easement only is owned by the D. U. W. Co. which is valued at $300 per mile or a total of $17,400. Making an average value for the rights of way of $50 per acre. The values to which I have testified are in my judgment the present fair market value of the lands for farming and grazing purposes. The total valuation of the several items concerning which I have testified is $235,625.

Mr. Charles W. Bowles was associated with me in the valuation of these lands. He inspected the lands with me and we agreed upon the values in each case. In placing the valuation on the conduit lands owned in fee we took into consideration damage to the owner of adjoining lands. But in no other case. Exhibits A5 and A6 showing lands acquired by the D. U. W. Co. subsequent to Jan. 1, 1908 and prior to Oct. 31, 1913, represent lands that are included by us in our valuation. Have been associated with and had experience with irrigation and water rights ever since my boyhood. There has been a marked increase in the value of lands since 1894. There was an increase between 1894 and 1907, it applied to lands in and about Marston Lake and in and about the Platte Canon works. I know of many cases where land values have doubled. I don't think that is true in all cases, there has, however, been an increase in all cases.

Cross-examination by Mr. Nye:

1894 was a particular low year in land values. It was perhaps 1897 before the lands got back to normal after the panic slump.

339 The fact that what are called bottom lands are sub-irrigated producing better feed had something to do with our valuing them higher than upland pasture lands. Parcel No. 8 in Item 34 and parcels 21 and 22 in Item 35 have not been sold. $75 an acre is not a special value for the Woodbury lands because of

its location and proximity to the city. We did not actually take measurements to determine whether the 40 inch conduit is on this 20 acre plat or beside it. All the other parcels in Item No. 34 are used by the conduit for right of way which varies from a minimum of 50 feet to a maximum of 200 feet, the latter occurring where there are valve houses and meters, etc., and only for short distances.

In the cases of the rights of way where we considered that there was no damage to adjoining lands we allowed none. In the case of the reservoirs and other works we did not take into consideration any effect upon adjoining lands. I visited the Platte valley ranches on June 19, at which time they had good crops and appeared to be well kept up. I have been familiar with them for 20 years. I made this valuation since this hearing commenced.

Dedirect examination by Mr. Dorsey:

In reproducing these rights of way either in fee or easements the question of damage to adjoining lands, must be considered and paid. Lands in the localities discussed were worth more in 1907 than in 1897 and are worth more now than in 1907.

Recross-examination by Mr. Nye.

There has been very little change in land values in the last few years.

Witness, ARTHUR D. WALL recalled.

Direct examination by Mr. Dorsey:

In valuing the Platte Canon Ranches we took the acreage of the different classes of land as given us by the Superintendent in charge checking it roughly by observation and also with the acreage heretofore fixed by other appraisers. The acreage in the Phebe Strong, William Strong and Becky Archer ranches agree with the acreage valued by McNeil and Sanborn in connection with the former appraisal. As to the Frank Archer ranch our irrigated acreage is 320 theirs 300 that additional acreage probably has been placed under the ditch. Our bottom land acreage is 42.6 theirs 35 acres. There is a difference of 12.40 acres in the total acreage of the ranch because a strip of land has been taken out for rights of way for cer-
340 tain conduits. I have prepared a list in the nature of an abstract of the various instruments by which the property constituting the water works system have passed from one company to another. Said abstract Exhibit A 62 offered and admitted. Exhibit A 63 is a similar abstract of instruments relating to the chain of title of the water rights of the D. U. W. Co. Offered and admitted. I have resided in Colorado 26 years and have been connected with irrigation matters ever since I came here. Was first employed in the office of a company making loans on real estate, afterwards by the Colorado Mortgage and Investment Company, the greater part of the time in charge of their lands and ditches and reservoirs. That is the company which built the High Line Canal. Since leaving that company about 7½ years ago I have continued

to deal in land and irrigation investments, particularly the latter. During that time have been a director or officer in one or more irrigation companies. So have been in touch with the management and operation of irrigation works and the purchase and sale of water rights. Been particularly in touch with these matters in Water Districts 2 and 8 immediately above and below the city of Denver. Also have some knowledge of water rights on the Cache La Poudre, Big Thompson, St. Vrain, Boulder Creek, Clear Creek and Bear Creek. Have been secretary of the Consolidated Ditches Company of District No. 2 for eight years. Am familiar with the priorities and the available water supply in Platte River, and with the lands to which the water of the river and its tributaries is applied or might be applied. Am familiar with the value of lands with and without water supply and with the value of water rights in this vicinity. Am familiar with Lake Cheesman, have visited the site before, during and since construction. On the basis of 60,000 acre feet annual yield, which figure is between the estimates of the two engineers who have estimated the yield from Lake Cheesman, I believe the water to be worth $60 per acre foot, or $3,600,000 for the entity, including structures, lands and water rights. Lake Cheesman being a stream bed reservoir has a great advantage over reservoirs not located in the bed of a stream.

The majority of the reservoirs in Colorado, I should say 95 per cent of them are not stream bed reservoirs. Nearly all irrigation reservoirs are created by earth dams. Cost of maintenance and operation of Lake Cheesman, the dam of which is of masonry, would be infinitely less than any reservoir I remember having seen. I am familiar with a number of such reservoirs.

The location of Lake Cheesman above the headgates of all of the ditches on the Platte River gives it another great advantage.
341 Water from it could be delivered to the headgate of any ditch desired on the stream without the formality of exchange and the attendant trouble. There are lands in the vicinity of Denver not now supplied with water or insufficiently supplied that would absorb the water from Lake Cheesman at the price I placed upon it. Am familiar with Lake Marston and with the Platte Canon, Bear Creek and Turkey Creek rights of the Water Company. Assuming that through a combination of the Platte Canon, Bear Creek and Turkey Creek rights and Marston Lake there could be made available from Marston Lake during each and every irrigation season 44,000 acre feet of water. I should consider those water rights and property necessary to produce them worth $2,400,000. It has been my business to be familiar with the flow of the Platte River above Denver for something like 20 years. I have investigated the various water rights of the D. U. W. Co. with a view of determining their yield.

Have gone over the figures of Mr. Geo. G. Anderson and have checked certain of his figures with records that I have kept myself. I have made my own analysis of the yield capacity of Lake Cheesman dividing the storage season on a different basis than has been used by others in their analyses. My division occur-ing in the mid-

dle of the irrigation season instead of at the beginning of the calendar year. Handled on that basis the reservoir produces a total storage of 870,000 acre feet in 14 years from 1900 to 1914 or an average of 62,140 acre feet annually. 1902 was a year of excessive drought which the intelligent farmer looks for once in awhile like a hail-storm or a pestilence of grasshoppers, and to meet which it would not be wise to make provision for excessive storage capacity. Eliminating that year the average annual yield from the reservoir would be 65,800 acre feet or 83 per cent of the total capacity of the reservoir. I have used as a foundation for my estimate the figures prepared and testified to by Mr. Anderson in this case. I have not made any computation on the basis of Mr. Comstock's figures. I know of no irrigation reservoir approaching the size of Lake Cheesman of equal efficiency, as compared with the total capacity of the reservoir. I am familiar with the yield capacity of the other water rights of the D. U. W. Co.

An examination of the records of the Platte River for the past 26 years eliminating the year 1902, show- there have been only three months during the irrigating seasons when the flow of the Platte River, fell below the point where the Platte Canon Ditch would be able to take its full capacity during the irrigating season. These three months were, Oct. 1889, Oct. 1901, and Oct. 1903. This ditch may therefore be assumed to have 100 per cent efficiency
342 during the irrigation season, which after deducting water for 300 acres under the ditch not owned by the D. U. W. Co. which must be supplied with water gives it an annual capacity in the irrigation season, of 22,500 acre feet, and in the non-irrigation season of 15,221 acre feet, after making deductions to cover the times when the ditch was not fully supplied, or a total of 37,500 acre feet per annum. To be used through Marston Lake, which with the supply from Bear Creek excluding the Soda Lakes supply would bring the total for that re-servoir to 44,300 acre feet. On which I have placed a value of $2,400,000 equivalent to $60 per acre foot for 40,000 acre feet.

Am also familiar with the supply from the Mississippi Street galleries, which I estimate to be capable of producing 7,700 acre feet during the irrigating season and 4,500 acre feet during the non-irrigating season or a total of 12,200 acre feet for irrigating purposes. The water in the irrigation season could be applied direct through ditches below Denver or by exchange with the stream through ditches above Denver. The non-irrigating season flow would have to be stored. Storage capacity is available below Denver. Have made similar investigations of the Platte Canon galleries. The irrigation season flow of which would amount to 4,200 acre feet, the non-irrigating season flow 2,700 acre feet or 6,900 acre feet per annum. The water could be made available in the same way as that from the Mississippi street galleries.

Have also investigated the yield capacity under the independent rights of conduits Nos. 2 and 3. I came to the conclusion, basing my judgment on the efficiency of flood water ditches, that these conduit rights could supply an average of their capacity for

30 days each season, making in round numbers 4,000 acre feet per year. Also investigated the yield capacity of the Cherry Creek galleries, and concluded that they are capable of yielding 3,400 acre feet during the irrigating season and 1,200 acre feet during the non-irrigating season, or 4,600 acre feet per annum.

In arriving at a value for the gallery and conduit rights I considered only the summer flow and placed on them a value of $500,000 including the structures necessary to divert the water, the valuation upon which is included in Exhibit C. Am familiar with the water rights listed as item No. 11, at page 117 of Exhibit C. This is a 50 acre water right out of the High Line Ditch, which I valued at $25 per acre or $1,250 for the right.

The total value which I placed upon all of the water rights that I have enumerated is $6,500,000. including the land and structures necessarily appurtenant to the handling of these rights. The value of those lands and structures as set forth in Exhibit C by Messrs. Metcalf and Anderson was $2,784,393. leaving for the water
343 rights alone a net value of $3,700,000. The market value of the 100 shares of the Harriman Ditch Company stock owned by the D. U. W. Co. is $30,000. $300 per share. This is already included in my valuation of the water rights for Marston Lake. The value of the 110 shares owned by the D. U. W. Co. in the Soda Lakes Reservoir and Mineral Water Company is $27,500. or $250 per share. I did not include the Soda Lakes supply in the supply that I determined could be obtained from Marston Lake. On the basis of market value the 72 shares owned by the D. U. W. Co. of the stock of the Bergen Ditch and Reservoir Company are worth $14,400 or $200 per share. The water yielded by these rights is used entirely for irrigation purposes and I did not include it with the city supply. I also investigated the capacity and efficiency of the Harriman Reservoir upon which I found a value of $34,000. Deducting $8,450 for the value of lands appurtenant to the reservoir leaves a net value for reservoir structures and water of $25,550. That is not included in the valuation for city purposes because the water is used entirely for irrigation purposes. It like the Soda Lakes right could be used for city purposes through Marston Lake if necessary. The 20 acre right out of the High Line Ditch for the Cherry creek land is valued at $25 per acre. It is used entirely for irrigation purposes and not included in the value for city purposes. Rights under the High Line Ditch are not considered first class water rights. Farmers owning them are supplementing their rights with reservoir rights. I do not consider myself competent to place a value on the power rights of the D. U. W. Co.

Cross-examination by Mr. Nye:

Have been connected with the Consolidated Ditches Company for 11 years, ever since it was organized. Have been secretary for 8 years. It is a protective organization embracing practically all of the ditches in District No. 2. 19 companies in all. Am familiar with their structures and rights and during the past 8 years have assisted in protecting those rights through litigation and otherwise.

We never had any litigation with ditches in District No. 8, but have had with ditches in the South Park Country in District No. 23. The ditches in District No. 2 have not all had a full supply of water during the past 8 years. The older ditches have but the later ditches have had a limited supply. The ditches in the 70's have not had a full supply and the ditches in the 80's have had a comparatively short supply.

344 It has not been short every year. They have not been short this year. As a rule the ditches in that district have sufficient capacity to carry their full decrees. I estimate that the rights of the D. U. W. Co. are capable of furnishing a sure supply of approximately 120,000 acre feet per annum. The land which would absorb that supply for irrigation lies adjoining the city of Denver, primarily on the east and north, or east and northeast. There is some land to the west. I don't know how much of that supply has been furnished annually through the system of the D. U. W. Co. to the city and county of Denver as a domestic supply. I should say that from ½ to 2/3 of the water furnished the City and County of Denver passes back into the river near Denver in the form of sewage and seepage. That all goes to help make up the supply for the ditches below Denver. I don't believe that a change from a domestic to an irrigation use of this water supply would effect the capacity of the rights of the D. U. W. Co.

I have not considered the duty of water in my estimate of value because I have assumed that this supply, capable of being delivered at any time and at any point on the Platte River, is more valuable as a supplemental than as an entire supply. I would want to provide at least 1½ acre feet in order to deliver the acre foot to the land. In fixing a value I assumed that the purchaser would pay the expense of delivery and absorb the loss. I am confident that there is sufficient acreage below Denver to absorb all of this water at the prices that I have mentioned.

The price of dry land around Denver depends entirely upon its location and various local conditions. It will run all of the way from $10 an acre up to several hundred. I would say that there are 5000 acres in the vicinity of Montclair and Aurora and between Denver and Littleton that is dry land, suitable for country homes, etc. that could not be bought for less than several hundred dollars an acre. The land that I have in mind extends out for a distance of perhaps 20 or 25 miles and runs in price from $10 an acre up to $100. The $100 an acre land would be adjoining or close to the city limits. The are perhaps 2000 or 3000 acres of this land. I don't know a piece of land capable of irrigation from the High Line Ditch that can be bought as cheap as $10 an acre. The entire eastern end of the State is physically under the High Line Ditch. I couldn't tell how long it would take to dispose of the rights of the D. U. W. Co. at $60 per acre foot. It would not take very long to develop the lands which would consume this water. A con-

345 siderable portion of the land is at least partially developed now. I satisfied myself that Mr. Anderson's figures which I used as a base were conservative. The quantity of water that I esti-

mated as available for storage was the quantity available during the entire year. Not only in the non-irrigating season. I made my figures from the middle of one irrigation season to the middle of the next, dividing practically at July 1st. I don't know how much water was actually stored in Lake Cheesman in each of those periods. It was full a considerable portion of the time.

I did not distinguish between storage in the irrigating season and in the non-irrigating season. In eliminating the year 1902 for the purpose of another consideration I looked upon that year and its unusual drought as a sort of calamity which occurs only once in a great while. The only year comparable with it so far as any one's memory goes being 1864. 38 years previous. On the same theory there would be no excuse for eliminating the highest stream flow, because after the reservoir was once filled it makes no difference if a million acre feet came down, it could not be taken. In a number of years there was available for storage more than the capacity of Lake Cheesman. In 1900 about double, in 1909 about 3 times, in 1912 about double and the present year. I assumed that 130 second feet must be passing Platte Canon in order to entitle the Platte Canon ditch to its full appropriation in the irrigating season. Practically no water would have to pass the ditch in the non-irrigating season. I assumed 100 per cent efficiency for the Platte Canon Ditch in the irrigating season. In the non-irrigating season the efficiency depends on the quantity in the stream.

In determining the efficiency of the Platte Canon Ditch in the non-irrigating season I deducted 10 per cent and the odd figures over even thousands, I did not make any assumption as to whether the flow from the infiltration galleries in Platte Canon was a part of the stream flow or was underground flow. The galleries are below the mouth of the canon some distance. I estimated their capacity at 4200 acre feet, during the irrigating season. That is approximately 10 cubic feet per second. That is the amount supplied on the average by those infiltration galleries. I would not know how to determine how much water would have to pass Platte Canon in addition to the supply of the Platte Canon Ditch to supply those galleries during the winter months.

In determining the quantities of supply from the Mississippi Street galleries and the Platte Canon Galleries, I assumed the use of water from those sources both in winter and in summer, and for the other conduits assumed the existence of rights by appro-
346 priation and actual application. Also that there was on an average a supply equal to the total capacity of those conduits one month each year. That was flood water, when every other appropriator prior in time had been supplied. I considered in that connection both the capacity of the canal 600 cubic feet and the amount usually drawn by the High Line Ditch.

I did not attempt any definite determination to ascertain on exactly what days that water would be available for the conduits. I simply used as a basis other flood water rights. The High Line is in that class. I did not allow for the High Line drawing 600 feet during all that period because in the actual operation of the ditch

it is not probable that it would draw its full appropriation. I managed the High Line for 13 years and I know that it does not always draw all the water it can get during the irrigating season. In fact today it is drawing about ½ what it could get under its priority because the water is not needed.

Lands under the High Line ditch have not a first class water right, because water is not available when most needed. The average quantity diverted annually is ample for the 30,000 acres provided with water rights, but it is not deliverable at the right time. The aggregate of all the values assigned by me was $6,501,250. That included the lands and structures directly appurtenant to the handling of the water. I included the headgates and the 60 inch conduit.

The net value of the water assigned by me was $3,715,607, which I treated as $3,700,000. The $15,607 thrown off would more than cover any small items of land that might have been omitted in estimating the extent and value of the physical structures appurtenant to the water rights. I assigned a total valuation of $500,000 for the water rights attached to conduits Nos. 2 and 3, and the three infiltration galleries. It would require storage to make available the winter flows from the infiltration rights. But in making my computations I excluded the winter flow. In considering the summer flow from these different sources I assumed that the flow would be constant throughout the irrigation season. It is true that some of the months of the irrigating season require more than one-seventh of the supply of the season. If storage were provided to so distribute the supply from the infiltration works, the value of the rights would be higher. I have only assumed that water would be available for such acreage as could be properly irrigated with that supply distributed in uniform quantities day by day. I have been employed by the D. U. W. Co. for about 3 months in connection with the preparation of the evidence in this case. I have gone to
347 other points outside of Denver and procured witnesses in the matter of water rights.

Redirect examination by Mr. Dorsey:

By procuring witnesses I mean that I had asked persons whom I knew to be experts in their line to act as witnesses in this case. I have a wide acquaintance among men connected with irrigation matters. By shortage of water in the case of the ditches in District No. 2 I meant that they did not have sufficient water for their needs. The 120,000 acre feet annually that I stated to be the available supply under the rights of the D. U. W. Co. include the 4,000 acre feet that I attributed to Conduits Nos. 2 and 3. The variation in price of dry land from $10 to several hundred dollars per acre, depended primarily upon proximity to Denver and transportation lines. Other local conditions had something to do with it.

Adjoining the city and convenient to transportation lines the lands afford locations for suburban homes, intense farming, etc. I am of the opinion that 1914 will prove to be the year of highest stream flow of which we have any record. I stated that 130 cubic feet per

second must pass Platte Canon before the Platte Canon ditch could divert its full appropriation. The 56. feet of the appropriation of that ditch is included in the 130 second feet. In the winter season the Platte Canon Ditch can take all of the water in the stream up to the 56 feet. The supply of the High Line Ditch would be an ample supply for 25,000 or 30,000 acres if it could be so arranged that the water was available just when it was needed.

Recross-examination by Mr. Nye:

I know that as a matter of practice for a long term of years the Platte Canon ditch has diverted up to the full volume of the river in the winter season and there have been no demands upon it to turn out water. I am basing my statement as to what it can do in the future upon what it has done in the past. I exclude the power rights because the prior power rights are owned by the same company, except as to one-half of the old Platte and Denver Ditch. The Smith Ditch is not ahead of the Platte Canon Ditch.

Redirect examination by Mr. Dorsey:

I am not aware of the provisions of the agreement that exists between the D. U. W. Co. and the owners of the other one-half of the power rights of the Platte and Denver Ditch.

348 Recross-examination by Mr. Nye:

The total water rights outstanding under the Highline Ditch are for a trifle over 30,000 acres. Of these I should say that all but 4,000 acres are in good standing.

Redirect examination by Mr. Dorsey:

I ceased to be active manager of the High Line Ditch about 8 years ago. I am still a director of the company.

Witness CHARLES W. BOWLES.

Direct examination by Mr. Dorsey:

I reside one mile west of Littleton. Have lived in Colorado since 1868. Am a farmer. Have been a member of the School Board in Arapahoe County three different terms and was county commissioner for eight years. Am familiar with the value of farm lands in that vicinity. I accompanied Mr. Wall in a recent inspection for the purpose of valuing certain lands said to be the property of the D. U. W. Co. We did not include the lands in the vicinity of Lake Cheesman.

The valuation placed upon the land was for farm and pasturage purposes, without regard to the use to which they are put by the D. U. W. Co. for water works purposes, except in the case of certain conduit lands. The lands and the values placed upon them are as follows: Item No. 2, 152.624 acres valued for pasturage purposes.

$765. or five dollars per acre. Item No. 3. 306.65 acres valued for pasturage with some tracts along the river suitable for farming at $10 per acre $3,065. Item No. 4. Platte Canon Reservoir Site, 1 parcel 7.768 acres valued at $115. Another parcel 85.25 acres valued net at $7,275, after deducting a water right for 50 acres from the High Line Canal. Item No. 5. Platte Canon Filter site, 3.22 acres at $100 per acre $320. 7 acres at $100 per acre $700 and 4.06 acres at $15 per acre $60. Item No. 6. 22.90 acres valued at $780 net after deducting water rights. Item No. 7. 19.95 acres $300 and 10.3 acres $155. Item No. 8. Lehow Lake 13.08 acres $520. Item No. 9. Phebe Strong ranch 680 acres, 126 acres of irrigated land valued at $150 per acre, $18,900. 554 acres of pasture land valued at $10 per acre $6540. Total $24,440 from which we deducted $7560 for the water right on 126 acres leaving $16,680 plus $1200 for farm buildings, making a net total valuation of $18,080. Item No. 10 William Strong ranch 280 acres 145 acres of irrigated land valued at $150 an acre $21,750. 75 acres of pasture land $10. $750. 60 acres of bottom land $20. $1200. Total $23,-
349 700, deducting $8700 for water rights for 145 acres, leaving $15,000 plus $800 for farm buildings, making a net total valuation of $15,800. Item No. 11. Becky Archer Ranch 160 acres 130 acres of irrigated land $150, $19,500. 20 acres pasture land $10. $200. 10 acres of bottom land $20. $200, making $19,900 total value, deducting $7800 for water rights for 130 acres leaving $12,100. plus $1000 for farm buildings making a net total valuation of $13,100. Item No. 12 Frank Archer Ranch 587.60 acres. 320 acres of irrigated land valued at $150 $48,000. 225 acres pasture land $10. $2250 42.6 acres bottom land $20. $850. Total $51,-100. deducting water rights $19,200 for 320 acres leaving $31,900. plus $6000 for farm buildings leaving a net total value of $37,900. Item No. 13 Mountain Reservoir Site. 810 acres at $7.50 $6,075. We found that a great deal of work had been done there towards the construction of a reservoir, but we valued it solely for pasturage purposes. The values that I have placed upon these lands are in my judgment a fair and reasonable market value on them at this time for agricultural and grazing purposes without regard to their use for water works purposes. Item No. 14. Harriman Ditch headgates. 11.84 acres $1000. This land is in the town of Morrison and would be valuable for resort purposes. Item No. 31. Jefferson, Harriman Ditch fencing this strip of land 20 feet wide three or four hundred feet long valued at $50. Item No. 15. Harriman Reservoir 130 acres $125 an acre, $16250. deducting for water rights for 130 acres $7800 makes net total value $8,450. Item No. 16. Marston Lake flume 7.58 acres runs through three fine farms, valued at $150 per acre $1137. Item No. 17 Marston Lake Reservoir 840.224 acres 740 acres valued as irrigated land at $150 per acre $111,000. 67 acres at $50 per acre $3350. 33 acres $10 an acre $330. Total $114,680. deducting water rights for 740 acres $44,430 leaving $70,-280 plus $1500 for farm buildings leaves a net total valuation of $71,780. There are a number of other buildings on this land used for water works purposes but we did not consider their value. I

may say in connection with the 67 acres that we valued at $50 an acre that I sold that land to the company and they paid a great deal more than $50 an acre for it. The values that I have given for these Bear Creek valley lands are in my judgment the present day fair market value, for agricultural and pasturage purposes. Not considering at all their use for water works purposes. In valuing Marston Lake, Harriman Lake and the Platte Canon Reservoirs. We valued them on that basis though they actually are used for reservoirs. We did not take into consideration the reservoir structures upon those lands. Item No. 19. Sullivan Reservoir site.
350 80 acres $25. per acre $2000. We found a large reservoir partly constructed on it but did not take that into consideration. The land lies under the Castlewood irrigation system and close to Denver. Item No. 20. Cherry Creek gallery lands 147.04 acres. 20 acres with a water right under the High Line Ditch at $100 per acre $2000. 40 acres along the creek at $50 an acre $2000. 87.4 acres creek lands $10. $870. Total $4,870, less $500 for the High Line Ditch water right making net total value $4,370, plus $1500 for three brick buildings in poor repair, making agreed total $5,870. Item No. 34. 40 inch conduit lands. We valued the 20 acres of the Woodbury tract at $75 an acre $1500. without water rights. That land can be irrigated from the Agricultural ditch it lies just east of Loretto College. Platte avenue runs along the north side of the land.

As to the acreage irrigated and un-irrigated on the different ranches we accepted the statement of the superintendent in charge for the D. U. W. Co., whose estimate I was willing to take. My testimony would be the same in all respects as the testimony of Mr. Wall with regard to the valuation for the rights of way owned in fee for conduit No. 3. Also as to Item No. 35, conduit No. 6 lands, and Item 36 conduit No. 7 lands. In valuing these lands we considered the damage to adjoining lands where there was any. Anybody attempting to obtain a right of way of this sort would be obliged to pay such damage. The amount of the damage we added to the acreage price of the land. The total value arrived at for the fee rights of way for those three conduits was $22,028. Item No. 37. Rights of way owned as easements. 58 miles valued at $50 per acre or $300 per mile. total $17,400.

The total valuation allowed for all of the lands outside of the city for farming and agricultural purposes, except as to the conduits, where damage to adjoining property was included was $235,625.

Cross-examination by Mr. Nye:

I think those lands would sell at the price placed upon them within a reasonable time. My father sold a good deal of land to the water company. The waste water from the Marston Lake filters supplies water to a small lake owned by me which I use for irrigation. I am neither a bond holder or a stockholder in the D. U. W. Co. At one time I owned some South Platte bonds which I received for some Soda Lake stock. That was in 1907 I think. I soon disposed of them.

The 11.84 acres in Morrison adjoins the buildings in the town, and runs up stream about a quarter of a mile above the town. The works of the water company occupy only a small portion of
351 the land. Unless the remaining land was used for protection of the intake works it is not in use at the present time in connection with the water system.

I consider the dry lands are worth the price we assigned to them.

Witness EDWARD R. CONAWAY.

Direct examination by Mr. Dorsey:

I reside in Denver. Have been engaged in the real estate business for about 2[illegible] years in Denver. Buying, selling and dealing in lands and lots in and about Denver. Am familiar with the value of lands and lots in and about the city. I have had experience in appraisals for various purposes. Besides private appraisals I was one of the commissioners for the opening of Cherry Creek Drive from Broadway to Colfax Avenue, and from Colfax Avenue to Blake Street, on the Colfax Viaduct Commission, and in behalf of the Burlington Railroad and the Moffat Railroad. I have recently investigated certain property said to belong to the D. U. W. Co. for the purpose of determining its present value. And have arrived at that value on the basis of so much land without regard to its use for water works purposes. The values arrived at are as follows: Item No. 21, Ashland Avenue Reservoir. 8.37 acres at $600 per acre. $5,022. There is a reservoir constructed on the property which was in no way considered in valuing it. Item No. 22 page 113 Exhibit C. The Ashland Avenue Pump Station 11 lots $1500. Item No. 23. De Lappe place pumping station site. 3 1/5 lots $200 a lot $640. Item 24. Cottage Hill Tank site, 43 lots $150 each total $6450. Item 25. West Denver Pump station. Item 26. Tail race from West Denver Pump Station, Item 27, Lake Archer Canal and Lands all of them contiguous property indicated on Exhibit A4, were valued as follows: Item No. 25, $48,570 No. 26, $9,432.50. Item No. 27 $212,,191.95 total for the three parcels 25, 26, 27, $270,194.45 (The value of each item included in the parcels is set out.) The value assigned is the land value alone without regard to the use to which the land is put or the fact that it constitutes a continuous strip, and without consideration of the fact that if one should undertake to reproduce a continuous strip like that damages would have to be paid to the owner of adjoining property which was cut up or otherwise injured. I have included nothing for the structures on the property. Item No. 8. University Park Tank Site, four lots, $75 each $300.
Item No. 29. South Denver Pump Station site 14 lots $75
352 each $1050. Item No. 31, storage tank site Highland park, 2 lots $250 each $500. Item No. 32. 46 lots in Cottage Hill, $150 each $6900. Item 32. 24 fractional lots adjoining Capitol Hill Reservoir, $350 for the whole piece. The values assigned are the reasonable market values at which the property could be disposed of in a reasonable length of time but not at a forced sale.

Cross-examination by Mr. Nye:

If the company was ready to sell and the buyer was ready to buy the prices that I have fixed would be the fair value for the property. I do not believe that the land adjoining the lands shown on Exhibit A. 4 constituting an equivalent strip could be purchased for the figures that I have placed upon this property. If another water company or a railroad wanted to come into the city from the south and paralliel this property taking an equivalent amount of land it could not be reproduced in my estimation for anything like that figure. It would cost much more. If I were to value that entire property as a unit I would put a greater value on it. Roughly perhaps 50 per cent more. That is only a guess. That property would be particularly valuable for a railroad right of way but I did not take that into consideration in determining these values. My valuation was simply on the separate parcels as if they were in the same situation as adjoining properties, absolutely without regard to the use to which the land is put. I valued the larger parcels higher proportionately than those that are split up into small parcels, because large tracts are always worth more than small tracts similarly situated. As to the portion lying south of Exposition Ave. which is 100 feet wide, I based the value on the acreage value of adjoining property. The 6.06 acres in the narrow strip south of West Exposition Ave., I valued it at $1250. an acre. It could not be used for anything except a right of way. The tail race item 26, was valued for just the acreage it contained. I valued that at $1750 an acre. It is more valuable as a right of way than for any other purpose. I just took the adjoining lot value and discounted that. I did not add anything to it for the special purpose for which it is used and I did not take anything from it.

Witness EDWARD R. CONAWAY recalled.

Direct examination by Mr. Dorsey:

In the 24 years that I have been in the real estate business I have had to do with loaning money and obtaining loans on city real estate. Before the panic of 1893 the loans of the firm with which I was connected ran into the millions, in recent years the
353 volume has decreased materially. I am familiar with the prevailing rates of interest on real estate loans. On business property I have had very few loans in recent years. On residence property the uniform rate for a number of years has been 6 per cent in addition to which the borrower paid a commission of 2 per cent and other expenses of the loan, examining and bringing down the abstract, recording, etc. Those loans generally are for three years. The value of the security is at least double the amount of the loans. Prior to that time the prevailing rate of interest was 8 per cent. That was true when I first came to Denver for all residence loans unless something very choice, when it might be had for 7 per cent. That rate prevailed until about 1896 or 1897. After which the eastern rates of 6 per cent gradually came into vogue. The prevailing rate of interest on surburban loans is 7 and 8 per cent.

Witness HARRY W. NEWCOMB.

Direct examination by Mr. Dorsey:

I reside in Denver. Am a real estate broker. Have been engaged in that business about 12 years. Am familiar with the value of lands and lots in Denver and its vicinity. Have had experience in valuing and appraising properties in Denver. Have valued Market Street property for the Burlington Railroad, gave testimony before the Broadway Extension Commission, Civic Center Commission, and the commission that had charge of the condemnation of Cherry Creek Drive. My principal business is loaning money for clients. My experience enables me to determine the value of parcels of real estate in and about Denver. Have recently inspected certain lands said to belong to the D. U. W. Co. for the purpose of valuing them. The values regarding which I am about to testify are merely land values and do not take into consideration the use to which the lands are put or the improvements thereon. The valuations upon the different parcels are as follows: Item No. 18. Littleton Mill Lands. Two parcels containing 3.51 acres have valued at $1800. The property is one of the main streets in the Town of Littleton. Item No. 21. Ashland Avenue Reservoir site, 8.37 acres at $700 an acre, $5,859. Item No. 22, Ashlannd Avenue Ave. Pumping Sta. site 11, lots at $125, $1375. Item 23 De Lappe place lots, 3 1/5 lots, $250 each $750. Item 24. Cottage Hill Tank Site, 43 lots, $150 each, $6450. In valuing Items Nos. 25, 26, 27, in the southerly part of the City and County of Denver I did not take into
354 consideration the fact that they constituted a connected contiguous and continuous, strip of ground available for right of way or other like purposes or the use to which they are put by the water company or any water company structures upon them. The basis of the valuation was the location of the ground and the surrounding land. The valuation of Item No. 25, was $53,800. Item No. 26, $11,982. Item No. 27, $209,239. The aggregate value for Items 25, 26, 27, $275,021. (The detail of the items is set forth.)

In valuing these items I did not take into consideration what it might cost to reproduce a similar strip of ground or the damages that would have to be paid to owners of adjoining land because of cutting up or otherwise damaging it by taking these strips.

Item No. 28. University Tank site 4 lots, $25 a lot $100. Item 29, South Denver Pumping Station site 14 lots, $50 a lot, $700. Item 31, Highland Park tank site 2 lots, $250 each $500. Item 32, Cottage Hill Lots, 46 lots, $150 each $6900. Item 33, 24 fractional lots, adjoining Capitol Hill Reservoir, $300 for the piece. The values that I have assigned are in my judgment the reasonable market values of those lands and lots.

Cross-examination by Mr. Nye:

The gross value assigned to items 25, 26, 27, is made up by the addition of the values I assigned to the separate parcels. If I had considered at all the fact that those items are contiguous, forming a stretch of land that might be used for a right of way, I would have

made a great deal higher valuation. If you attempted to parallel this strip of land you would have to pay many many times this amount. At least three times the amount. For illustration, we sold the Post Office site to the government and where in one case we had an option on one lot at $6000 an adjoining lot, the same kind of a lot we had options on at $25,000. You could have gone across the street and bought lots for much less. Wanting one particular parcel in one particular location we had to pay four or five times what it was worth to get it. The property could be condemned but it is pretty hard to tell where you would land then. If you paralleled this strip of land you would have to go through the Rio Grande shops and it might cost you a million dollars to go through there alone. On the other side are factories and foundries. It is a manufacturing district to a certain extent. I think to reproduce this particular tract would cost three times, yes five times the value I placed on it. Take the Civic Center for example, it cost five times what the ground is worth. My values are based upon the surrounding property. Some of this land is good for celery beds and
355 adjoins celery beds, I valued it accordingly. Some of it adjoins the Rio Grande yards and some day will be sold to the Rio Grande for yard space. I took into consideration that fact. I am not a member of the Retail Association of the Chamber of Commerce. I am not interested in the Denver Union Water Company in any way. Only I pay them pretty good water taxes which I will be glad to see reduced. I have held up about $5000 that I have refused to pay them and I am going to see how you come out before I pay them too. I told them to go ahead and turn off the water if they wanted the money. They have not turned it off on me yet and I am still carrying the money. I have no love for the water company. I estimated the land as an appraiser and an uninterested party. I think I have given the people the best end of it.

Witness WILLIAM W. WATSON.

Direct examination by Mr. Dorsey:

I reside in Denver, where I have been engaged in the Real estate business for 28 years. I am familiar with the values of lots and lands in Denver and this vicinity. My attention has been recently called to certain real estate said to be the property of the D. U. W. Co. so that I might determine the value thereof. The values are as follows. Item No. 18, page 112, Exhibit C. Littleton Mill property, 13½ acres valued at $4450. Item No. 21, page 113, Exhibit C., Ashland Avenue Reservoir site. 8.37 acres valued at $6,696. The values that I assigned are merely land values without regard to the use to which the land is put by the water company and based upon the value of adjoining and adjacent lands for general purposes. Item 22. Ashland Ave. Pump Station site. 11 lots, valued at $1650. Item 23. De Lappe place lots, 3 1/5 lots, $640. Item No. 24 Cottage Hill Tank site, 43 lots, at $175 a lot, $7,525. Items 25, 26, 27, being the West Denver Pumping Station, and Lake Archer and canal lands, shown on Exhibit A.4. colored either

red or yellow, valued without regard to the use to which the land is put or to the fact that it is a continuous strip of land and without consideration of structures of any sort whatever thereon. Item 25 valued at $53,800. Item 26, $10,780. Item 27, $194,055. Making the aggregate value of items 25, 26, 27, $258,635. land value only. Item 28, University Park Tank Site. 4 lots, $75 each $300. Item 29, South Denver Pump Station site, 14 lots, $1500. Item No. 30, office and superintendent's residence at Littleton, 20
356 lots, $3,250, without improvements. Item 31, Highland Park Tank site, 2 lots, $300 each $600. Item 32. 46 lots in Cottage Hill, $6,325. Item 33. 24 fractional lots adjoining Capitol Hill Re-ervoir $450. for the total. The values that I have assigned are the fair and reasonable values as land or lots only.

Cross-examination by Mr. Nye:

I did not take into consideration at all any value that parcels 25, 26, 27 might have as a right of way. As such it is worth at least three times as much. I think that land could be disposed of for a right of way, not right now, but I think within a reasonable length of time. A railroad right of way could be reproduced there for less cost than a water works right of way, because the railroad would increase the value of adjoining property as trackage.

I valued the same land during the appraisement of 1907-1909. I appraised this time without regard to my former appraisement. I have not compared this appraisement with my former appraisement. I am not interested in any way in the Denver Union Water Company. I was real estate manager for Mr. Cheesman, the former president of the company. Since his death I have continued to manage the real estate belonging to his estate. This connection has not in any manner biased or prejudiced my opinion in any way in this matter. I know I have given a fair and impartial valuation.

Witness LEONARD METCALF.

Direct examination by Mr. Dorsey:

I am a Civil Engineer, reside at Concord, Mass.; received my education at the Massachusetts Institute of Technology at Boston; am a member of the firm of Metcalf & Eddy, with offices in Boston. Our practice is chiefly along the lines of water works construction, the administration of some public utilities, water and electric light and power, and sanitary engineering lines and sewage disposal. Began experience in 1888 in office of Wheeler & Parks, builders and operators of water works in different parts of the country; returned to their office after graduating and remained on their construction work in different parts of the country for 3 years. Had charge of Department of Mathematics and Engineering and Meteorological Bureau at Massachusetts Agricultural College for 2 years. Began private practice in Boston in 1897 and 10 years later took into partnership Harrison P. Eddy, Worcester. Have advised a
357 number of cities and water companies in regard to construction matters and operation and designed and supervised the

construction of a great deal of work of that sort in different parts of the country. Investigated the operation of the water, sewer and street departments for the Boston Finance Commission; the Scranton and allied water companies, the Wilkesbarre and adjacent water works in Pennsylvania; have served the Indianapolis Water Co.; the New Jersey General Security Co. which supplies Paterson, Passaic, West Orange, Bloomfield, etc.; San Antonio, Texas, and a number of others,—some 75 or 100 different water works properties in different parts of the country; works in Cuba, Costa Rica and Porto Rico; have done some power work and served in litigation in the water works field both for the cities or water districts and for water companies in different parts of the country. Served on a number of Maine water district cases,—at Portland, Livermore Falls, Kittery, Rumford Falls and Waterville, Maine,—for the municipalities in those cases. Served as commissioner in one of the Massachusetts Metropolitan water diversion cases, and at Macon, Georgia.

For some 9 years had charge of the operation, rehabilitation and sale of 6 or 7 water and light plants in different parts of the country, more particularly the middle west, and operated them until I sold them for the bondholders, and had general supervision of several others for the bondholders when questions were at issue. Have investigated and determined the values of water works properties in some 35 or 40 cases in connection with condemnation or rating proceedings, or for different banking houses or prospective purchasers. The most important of these were the State of Maine cases; the plants supplying Scranton and Wilkesbarre, Penn. and environments; those of the New Jersey Security Co.; Macon, Ga.; Baltimore County, Maryland; Des Moines, Ia.; the Spring Valley Water Co., supplying San Francisco, Cal.; San Antonio, Texas; Indianapolis, Ind.; etc. Have acted both for the companies and in other cases for the cities or municipalities.

Was recently called upon to value the works of the D. U. W. Co.; first two years ago in connection with certain questions relating to the water rights of the Company and the use of Lake Cheesman, and in the fall of 1913 was recalled to Denver to assist in the preparation of data for the Board of Engineers of the Public Utilities Commission of the City of Denver, to inventory the property and determine its value for the company. This work began about October 2nd or 3rd, 1913, and barring one or two short absences, I remained here on that work until the middle of February, when I completed the investigation. I returned for this litigation three weeks ago.

358 In connection with making a complete and independent inventory and valuation of the works I inspected and investigated the condition of the property as to its efficiency, etc. The work was done in collaboration with Mr. George G. Anderson. We were assisted by Mr. William T. Barnes, my Chicago partner, who took immediate charge of the preparation of the inventory under my direction. We employed an engineering force of between 20 and 30 men for a period of about 3½ months to make the necessary surveys, examinations, drawings, tabulations, etc. incidental to the preparation of the inventory which resulted in the volume presented

in this case known as plaintiff's Exhibit C. We also prepared a large number of schedules for the engineers of the Public Utilities Commission whose investigations, embodied in their independent report, were carried on concurrently with ours, though they began 6 weeks earlier.

I prepared the table headed "Assessed value of property in Denver" at page 11 Exhibit C. Also the table "Approximate capacities of the plant of the D. U. W. Co." at page 12. It sets forth accurately the facts purported to be set forth, except one or two minor corrections, which I desire to make this morning.

I have prepared a duplicate of Exhibit C in which has been placed the valuations, figures upon depreciation, and all other matters pertaining to value which were left blank in Exhibit C originally filed with the court. This volume substituted for the original Exhibit C. Offered and admitted. The tables at page 12 of this volume concerning capacities correctly set forth the facts according to my best judgment and belief. I prepared the tables on page 13, of Exhibit C headed "Forecast of Water consumption." It is illustrated by the chart opposite page 3. With Mr. Anderson's assistance I prepared the table on page 13, headed "Safe Yield from Water sources for irrigation purposes." The tables at pages 22 and 23 dealing with seepage and evaporation from Marston Lake were prepared by me or under my supervision. They accurately set forth the facts dealt with. Plate VI a mass diagram of the natural yield of certain streams was prepared by me or under my supervision.

The last three columns of the tables dealing with the capacities of the supply mains of the D. U. W. Co. appearing at pages 41-43 of Exhibit C were computed by me, using the Hazen and Williams Formula for capacities, which is very generally used by engineers. Tables offered and admitted. I caused to be inserted the figures dealing with price and amounts in the tables at pages 99 and 100 of Exhibit C headed, "Property abandoned or no longer used in the service of the public." I caused to be prepared the tables from pages 101-104 of Exhibit C showing schedules of water rates, in effect from 1890 to 1914. The information was taken from the published
359 schedules of the water company. The tables from pages 105-107 dealing with physical and financial statistics, of the water system from 1895 to 1913 with the forecast beyond 1913 were prepared under my supervision. These tables were prepared as a result of such investigation as was necessary to disclose the information therein set forth.

The financial data in these tables does not take into consideration any allowance for depreciation. Pages 105-107 offered and admitted. Pages 100-*a* and 110-*b* cover corrections of some errors in the footings in the typewritten portion of this volume. The total correcion amounting to the sum of $4,547 which should be added to the gross reproduction cost of the property shown elsewhere. As a result of my investigation of this plant I have come to the conclusion that the plant is in excellent condition, the quantity of water available is prudently in advance of the needs of the community, the pressure under which water is furnished is good, comparing very

favorably with the records in the majority of our American cities. By this I do not mean to imply that there may not be some individual cases at the peaks of the different services where pressure is not as great as might be desired but broadly speaking it is a good one. In general I believe that the service furnished by the D. U. W. Co. compares very favorably with that furnished by any other water works system in the country. (Description of the system and method of operation, supervision of water supply from view point of health, etc.)

Their practice in the matter of supervision of water supply is good. Lake Cheesman is an unusually advantageous reservoir. The dam site being such as to give large storage for the amount of masonry and expense involved. The dam is the finest piece of masonry that I have ever seen in the world for the purpose. Marston Lake is also an advantageous reservoir in close proximity to the city. It will be used for a great many years as the principal distributing reservoir of the system. Storage is cheap and the elevation at which the water is held is advantageous. It is in no way undesirable. The use of hypochlorite as one means of purifying water is an accepted and approved method and in common use. It is used by the D. U. W. Co. in connection with the filtration system. The tables beginning at page 62 of Exhibit C headed "Summarized statement of gross reproduction cost, annual and accrued depreciation and net physical value of the property of the D. U. W. Co. estimated by Metcalf and Anderson as of Oct. 31, 1913." Show briefly all of the facts relating to reproduction cost, overhead charges, and all such items bearing upon the different elements of the plant as are necessary to be known to determine its value. The estimates upon which
360 these tables are based are set forth in greater detail later in the book. The property for convenience is divided into different classes. A and B applying to lands and water rights, and the other classes to segregations of the property by operating divisions.

Depreciation allowances are based upon the sinking fund theory with a 4 per cent rate. The accrued depreciation shown by the tables is exclusive of property abandoned or no longer in use. Interest during construction is shown on page 64 as one class. Detail- of methods of determining depreciation allowance are shown by the tables at page 65. I outlined the classifications by which the property is divided in Exhibit C using in a general way the classifications under which the company has operated. They are designated by the letters of the alphabet, Class A relating to lands and their values, beginning at page 111 of Exhibit C. The descriptions here are general descriptions by items. References are made by these descriptions to exhibits occurring at page 399-427 which give the specific description of the lands in each instance. In general the land values assumed by us are the average of the value testified to by witnesses in this case with an overhead allowance for legal and engineering expenses and contingencies of 10 per cent upon all the lands except Lake Cheesman. In the cases of lands used for specific water works purposes we have valued them for those purposes according to our judgment using the valuations of the witnesses as a basis.

Exhibit A8 shows the land values outside the city. The items correspond with similar items in Exhibit C except that it separates the lands outside the city from those within the city. Offered and admitted. Exhibit A9 shows the values placed upon the land within the city by Messrs. Newcomb, Conaway and Watson, the averages of the three and the value accepted by us for these lands. Offered and admitted. The addition of ten per cent for legal, engineering and contingent expenses is a proper allowance because a corporation such as this always does suffer such expense in gathering and assembling such property. The total valuation placed upon Lake Cheesman is about $3,400,000 including lands, structures, and all overhead charges. Valuation allowed for the lands was $200,000. In a general way this allowance is equivalent to $200 an acre upon the lands submerged and a nominal allowance approximating the cost of the lands outside of the water surface. It makes little difference what exact value may be placed upon the lands because the total value is in the entity and if land values were reduced, water right values would be increased. In the case of the Marston Lake Reservoir site we assigned a value of $168,000 as against a land value testified to by Messrs. Wall and Bowles of $71,780. Their valuation gave no con-
361 sideration to the value or use as a reservoir or the difficulty of assembling land for such purpose. The allowance is approximately $200 an acre. The same conditions prevail here as at Lake Cheesman. The total value is in the entity. A decrease in the allowance for land would result in an increase in the allowance for water rights. So the total value would amount to the same sum. It is common experience in assembling a body of land for such purposes that the cost is certainty two to three times as much as the land only in separate parcels. The element of damage is certainly an element of cost. Of the city lands, Items 25, 26, 27, are the same parcels shown on exhibit A4. To these lands we assigned a value of $271,094 which is lower than some of the values testified to by witnesses. It seemed to us for the purpose of a rating base, fairer to assign this value considering the uses to which they are put than the larger value which they might possess for some other use.

These lands are actually worth in the plant considering the service they perform the price that we have placed upon them. As to Class B water rights, the valuations are primarily the work of Mr. Anderson. I have gone over the matter sufficiently to determine that the values are reasonable. Therefore, they are included in our joint report. Fundamentally they are based upon the value of water in this vicinity for irrigation purposes. I consider that they are worth more for domestic than for irrigation purposes. Class T at pages 391-395 of Exhibit C and supported by an inventory beginning at page 821, covers the materials, furniture, tools, etc., used in connection with the system. The valuations assigned to the several items represent the judgment of Mr. Anderson and myself upon this class of property. Classes C to S cover the various structures and the details asset forth in the tables of summaries and at pages 119 to 390 of Exhibit C are correct statements of the determinations of Mr. Anderson and myself as to the extent and value of the several items.

In connection with these structures we have allowed in the gross reproduction cost 12½ per cent for engineering and contingencies, based on experience and judgment that the allowance is a reasonable one. Such expenses are incurred. These are matters of judgment and experience. After determning the gross reproduction cost, the next step is to determine the depreciation which the various elements of the property have suffered. We did that, taking into consideration both the physical depreciation or wear and tear of structures, and the functional depreciation, obsolescence, etc., which result in the abandonment or displacement of structures, for such reasons as changes in the art or changes in the conditions under which the company operated. In the final analysis I think the determination of depreciation is a matter of judgment which may be
362 checked as an aid to judgment by applying the sinking fund method of computation to the life assigned. In using the sinking fund method here I have used the 4 per cent basis which I consider conservative. We also have used in our determination the total cost of the item without consideration of the scrap value that might inhere in it, tending also to conservation. Based upon this assumed annual allowance the determination of accrued depreciation is a mere matter of computation to determine the amount that he accrued within the age of the different elements of property. The fair allowance for depreciation as I figure it in this case is $138,000 a year for physical and functional depreciation, and $30,000 a year for contingent depreciation. Making a total allowance of $168,000 a year. Exhibit A10 a series of blue prints, pages 62-97 contains a tabulation, of depreciation allowances based upon the present net reproduction cost of this property. The final result is identical with the results shown by Exhibit C but the method is different.

Annual depreciation allowance will generally lie at from 8 to 10 per cent of the gross revenue of the property. The accrued depreciation to date on the property now in use is found to be about $1,500,000. In addition to this there has been abandoned, property to the amount of approximately $1,250,000. So that the total depreciation, which this property has suffered up to the present time is estimated, at approximately 2¾ millions of dollars. I think the depreciation allowance made by me is at least enough. I may have deducted more than enough. For the next five to seven years I should consider ten per cent of the gross revenues of this plant a fair allowance for ordinary depreciation and an additional allowance of $30,000 a year, for contingent depreciation. In arriving at the reproduction cost of this system we have attempted to follow what the Wisconsin Railway Commission has defined as normal prices, such as might be obtained under fair competitive conditions were the work done under contract. In such items as cast iron pipe on which the market fluctuates more or less violently we have taken the average prices for the last ten years. As to the cost of doing the work we have interviewed contractors, examined contract figures and given consideration to the cost of work done by this company in the past five years. Exhibit A10 offered and admitted. The unit cost assumed for cast iron pipe was $32 a ton f. o. b. cars Denver. In the

distribution pipe system we added a $1.25 per ton as the cost of hauling, which brought it to $33.25 at the trench. In my judgment that is a fair allowance for the cost of handling. The entire determination at which we arrived was the reproduction cost
363 of the identical works less depreciation. Exhibit A11 contains the essential consideration upon which we based the unit cost for cast iron pipe. Offered and admitted. Exhibit A12 shows in detail the cost of pipe laying work done by this company during the past five years, the location and extent of the work, with brief notes concerning the character of soil, etc., exclusive of overhead charges, such as engineering, supervision, and inspection. This work generally has been done in the outlying districts of the city. These costs were one of the considerations that aided us in arriving at final judgment as to unit cost to be applied to the distribution pipe system. In the estimate of cost of the distribution system we included the cost of cutting, removing and replacing, existing pavement. Exhibit A13 is a summarized statement of the cost of pavement work according to the various classes of pavement. Exhibit A13 offered and admitted. Exhibit A14 gives the estimated cost per foot of trench for the pavement work over pipes of various diameter. They are the unit costs which we used in determining the reproduction cost of the system. They were arrived at partly on information furnished by Mr. Hunter, City Engineer, and officers of other public service corporations, to which we applied our judgment, arriving at these figures. Exhibit A15 shows the bases used by us for estimating the reproduction cost of laying cast iron pipe in Denver, the weight of pipe, assumed trench width, cost of all items connected with pipe laying, total cost of laying, with an estimate of additional cost to cover difficult work. It is prepared in such form as to be readily compared with similar data offered by the Board of Engineers of the Public Utilities Commission. Exhibit A14 and A15 offered and admitted. Specials are the fittings used in connecting and putting the pipe together.

The allowance for pavement in determining reproduction cost was based on theory that to reproduce the present system it would be necessary to cut the pavement wherever pipes occur. We also made extra allowance for the expense of crossings under streams, ditches, railroad and street railroad tracks and crossings. The net reproduction cost of these three items, pavements, parking, and special crossings, amounts to $656,205. Anyone attempting to reproduce this plant would encounter those obstacles and have to pay the cost of meeting them. It is my understanding that the reproduction cost theory involves the reproduction of the identical plant. That is what we did in this instance. We allowed in connection with the distribution pipe system a valuation for the service connections. Page 64, Exhibit C. By service connection we mean the tap in the main and the corporation cock controlling it, which has become a part of the pipe system and cannot be removed because it
364 would not be possible to control the water without it. The gross allowance for this item was $140,038. Exhibit A16 is a memorandum of the cost of wood stave pipe material for a

period of years, upon which we based our unit prices. We assumed on the lumber the price of $37 per thousand feet delivered, on the bands, and clips, 2.6¢ per pound f. o. b. cars, and on shoes, 3.9¢ per pound, f. o. b. cars. These prices were based on the average cost over a period of years.

It affords a greater stability to take the fair normal prices for a period of years, than to value a plant year by year on the prices then prevailing. Exhibit A16 offered and admitted Exhibit A17 gives data concerning the banding of wood stave pipe. At the bottom in tabular form are the costs assumed by us. Exhibit A17 offered and admitted. Exhibit A18 shows in graphic form the cost per linear foot of wood stave pipe as estimated by us, it excludes the cost of special structures, such as bridges, culverts, extra concrete at bends, etc., which in general increase the cost shown about one-third. It also gives a comparison with the costs arrived at by engineers' of the public utilities commission, being 8 per cent greater than their cost on gross reproduction and less than 5 per cent greater than their cost on net reproduction. Those figures were made independently neither set of engineers knowing where the other was going to land.

The gross reproduction cost excluding interest during construction on the structures, Classes C to S determined by us was $10,589,683. to that we added interest during construction, $964,293. which is 8 per cent of the gross reproduction cost of the items cited plus the land and supplies. Interest during construction represents the charge upon the money borrowed for the creation of such a plant as this for such period as the money would be tied up in structure under way until the structure actually went into use. It is an actual cost to which one undertaking such construction is put. The item of $120,000 occur-ing on page 64 Exhibit C designated "Organization and preliminary expense" is assumed to cover the expenses of preliminary investigation, legal work, filings, etc., incurred incidental to an investigation of the project and organization of the corporation.

That amount was added to the gross reproduction cost. As shown at page 64, Exhibit C there was also added to the gross reproduction cost of the structures lands to the amount of $920,103. Also Class T stock and supplies valued at $247,883. making a total gross reproduction cost for physical structures plus interest during construction, preliminary expenses, lands, and stock and supplies, of $12,841,-962. To which is added Class B Water rights, $3,530,000 365 making another total of $16,371,962. Finally there is added as shown on page 64 Exhibit C as going concern value $1,200,-000. That is the value present in a plant that is operating with attached business and an established income, over and above the value in an exactly similar plant in exactly similar physical condition not operating and with no business attached.

Exhibit A19 consisting of 11 pages, shows various computations. of the element of going value. The first computation is on the basis of the assumption by the Public Utilities Commission Engineers corrected to follow the Wisconsin Railway Commission theory which

produces a value of $1,710,000. The second method is substantially identical with the first except for some revision in the revenue and operating expenses as shown in detail by table 2, and results in a value of $1,920,418. The third computation is on the basis assumed by the Public Utilities Engineers corrected to follow the Wisconsin Railway Commission theory including in the base, new construction from earnings reported by the company since 1895, and results in a value of $5,778,000. The fourth computation is exactly similar except a 6 per cent rate of return is assumed instead of 7 per cent. which results in a value of $1,721,000. The Public Utilities Commission Engineers assumed a rate of return of 7 per cent and 1 per cent for depreciation. Objection to inquiry as to amount of development expense allowed by Public Utilities Commission Engineers overruled. Exception. The allowance by the board of engineers of the Public Utilities commission for development expense was $375,628.

The second page of Exhibit A19 shows in diagramatic form the forecast of the revenues and operating expenses of the existing plant, estimated for a period of five years from Oct 31, 1913, to Oct. 31, 1918 compared with a theoretical plant, the construction of which was commenced on that date for the purpose of showing graphically the time that would be required for the theoretical plant to develop the same revenue as the existing plant. Operating expenses are similarly shown.

These diagrams illustrate the meaning of going concern value in the existing plant. To test these figures they have been reproduced in tabular form at pages 105-106-107 of exhibit C where tables show the actual gross revenue per capita for the years 1905 to 1913, gross operating expenses per capita exclusive of fixed charges and depreciation upon the existing plant for the years 1905-1913, and the actual net revenue per capita for the same period. The figures carried forward in the diagram are based upon these tabulations. Columns 2-6 on page 5 deal with the financial statistics of the existing plant for the assumed period required for the development of
business and construction of the new plant, such as revenue,
366 operating expenses, taxes depreciation, and net revenue.
Columns 7-11 contain similar data relating to the theoretical plant. Column 12, shows the excess of the net revenue of the existing plant over the net revenue of the theoretical plant under the leaflet rates. Having in mind this comparison we assume that the investor builder who has an option at the date of valuation to either buy the existing plant or construct a new one, has in hand a sum of $15,850,000 which would cover the physical property, including water rights, interest during construction and the going concern value. If he buys the existing plant he immediately derives the revenue established and has to meet operating expenses, fixed charges and depreciation. If he builds a new plant he begins to make his plans, then spends his money in the building of the plant and the development of business. At the end of five years it is assumed the structural plant is complete. It is further assumed that it began to earn revenue in the second year after construction commenced.

The revenue of this plant overtakes the revenue of the other plant at the end of an 8 year period or 1921. Allowance is also made for the earnings upon his construction funds which must be kept in liquid form until construction is complete. The total structural cost is not complete until the year 1918. The total interest so earned upon the unemployed capital is shown in column 9. Interest during construction is allowed for the new plant which is shown in Column 10. This allowance tends to reduce the going concern value. In Column 12 is shown the preliminary excess net revenues of the existing plant over the new plant, the final excess revenues of the existing plant over the new plant are shown in column 13.

From these bases is obtained the present worth factor. In the next column is found the amount obtained by applying the factor to Column 13. The last column shows the cumulative amount to be $978,000. I estimate therefore that under the assumed conditions of acquisition of income indicated by the diagram and these tables that the going value would be approximately $980,000. In paragraph 6, page 1, of Exhibit A19 I have assumed a revenue to be made up of existing operating expenses, the same allowance for depreciation and a 6 per cent return upon an assumed value of the property of $15,500,000, instead of the actual rate of return enjoyed by this property. This is equivalent to an increase in the return for the year 1913 of $152,000, and results in a going concern value of $1,630,000. If seven per cent is assumed to be the fair rate of return upon the fair value of the property of $15,500,000 then the going concern value based in other respects upon the same figures shown in the tabulation would be $2,080,000. Within my experience going concern or development expense allowances
367 have run on the larger plants from 10 to 15 per cent of gross reproduction cost and upon smaller plants somewhat more. I do not remember ever getting a result less than 10 per cent and I have gotten results and seen other engineers get them as high as 20 per cent.

Taking 10 per cent of the net reproduction cost upon this property would give us $1,600,000 and upon the gross reproduction cost approximately $1,700,000. In paragraph 9 of Exhibit A19 is shown the going concern value upon the assumption that it was equal to one year's gross revenue. In other words, $1,386,000, under the leaflet schedule. In general, within my experience, the going concern value has been found to lie between 1 and 1¾ times the gross annual revenue of the property. The larger amount generally being found in plants requiring a long period of construction and in which the rate of acquisition of the business for one reason or another, such as a bountiful supply of ground water, would be likely to be long. As a result of these studies in this region where I believe the rate of acquisition of the business would be more rapid than normally found in this country, I have assumed the going value of this property to be $1,200,000. I believe that the actual development expense in this plant has been substantially more than that. I have now referred to all of the tables contained in Exhibit A19 except sheet seven, which refers to interest during construction.

In columns 1-10 of that sheet are references to the different classes of property included in the plant, with the years in which it is assumed the construction expenses will be incurred, worked out on the basis calculated to produce the most economical ultimate result. Column 11 shows the rate at which the investment is assumed to be made. Column 12 the amount to date. Column 13 the average amount upon which interest during construction is chargeable for one full year, and in column 14 the amount of this interest as figured at the rate of 7 per cent per annum. The total interest charge is equivalent to 7.93 per cent of the construction cost. I therefore have assumed 8 per cent as a fair allowance for interest during construction upon the entire cost of reproduction of the structures, lands, and water rights of the property. In columns 16 and 17 are shown the revised net construction cost assumed, including the interest during construction item, and based upon this assumption of an 8 per cent interest during construction allowance. This is the basis upon which I arrived at the rate for interest during construction on the reproduction cost of this property.

I have applied this average factor 8 per cent to the entire property because it is easier in computation. The rate is low
368 on such items as must be acquired at the beginning of construction and high on such items as do not tie up capital for a considerable length of time. For instance, in the acquisition of land by the Massachusetts Metropolitan Water Board the interest during construction item amounted to nearly 30 per cent of the cost of acquisition of those lands. The application of the average factor produces exactly the same result as the application of the actual rate to each class. The net construction cost items on sheet 7 exhibit A19 do not correspond with the final figures on this plant because the computation was made in advance of completion of the other report. It is close enough so that it has not appeared necessary to recompute them as the final results would not be affected. I believe that in computing the going concern value on the basis of the acquisition of income by a theoretical plant I have assumed a more rapid acquisition of revenue than could actually be realized in practice. That would tend to reduce the going concern value. As a result of all of these investigations and computations it is my judgment that the going concern value of this plant is $1,200,000. The other figures are merely made from various view points with the idea of trying at final results from a consideration of all of them. Exhibit A19 offered and admitted. The difference between my first computation of development expense on page 6 Exhibit A19 and the computation of the Public Utilities Commission Engineers develops from the fact, that I carried forward the deficits and surpluses after the manner used by the Wisconsin Railway Commission, the return being figured upon the capital sum thus adduced, the surpluses themselves enjoying annual accretions the deficits being added to capital account and the surpluses subtracted. This was not done by the Public Utilities Engineers. In computation No. 3. I followed the same method except that I added to capital account additional construction made with funds realized other

wise than by the sale of bonds. That is the method employed by the Wisconsin Commission. That was not done by the Public Utilities Commission Engineers. The term weighted age used in connection with depreciation at page 66 of Exhibit C and elsewhere means practically the average age of items in the plant similar in character that are being constructed continuously from year to year during the life of the plant, such as distribution pipe. The same methods were used in arriving at unit costs of all parts of the plant as have been explained with reference to the distribution pipe system and the conduit system. After ascertaining the unit prices to be applied the quantities were ascertained from measurements, checked against the records of the company and our assumptions as
369 to reasonable width, depth, etc., in the case of trenches and like work. I have given consideration to the operating expenses of the D. U. W. Co. Exhibit A20 shows the revenue and operating expenses of the company from 1895 to 1913. I believe that a fair amount to be expended by this company for operating expenses, including taxes, but excluding depreciation, for the year 1914, is $500,000. approximately $380,000, exclusive of taxes. For the year 1915 I assume that it will be about $50,000 less because I assume that there will be no such expenses as there have been this year in connection with the investigation of the Public Utilities engineers and the rating case. In my judgment those estimates are reasonable allowances for the operation of this plant. The estimates for the future are on the theory that the company will not have any more special litigation. Exhibit A20 offered and admitted as the basis for Mr. Metcalf's testimony subject to proof by an accounting officer of the company.

We made no allowance in the case of the Lake Cheesman land for engineering, legal expenses or contingencies, but allowed interest during construction to the amount of $16,000. That was at the average rate of 8 per cent adopted as the interest during construction factor on the entire plant. Considered by itself it was not sufficient to cover the interest during construction on that item. The abandoned property listed in Exhibit C. was not considered in either the gross or net reproduction cost. The only consideration given it was in connection with the matter of depreciation on the entire plant and it was independent of and in addition to the depreciation allowance on the existing plant. Its consideration simply gives a more accurate check upon the fairness of our depreciation allowance. The gross reproduction cost found by Mr. Anderson and myself was $17,571,962. the accrued depreciation $1,533,583 and the reproduction cost less depreciation $16,038,379. to which should be added the correction item of approximately $4500 shown on pages 110-a and 110-b. On page 64 of Exhibit C. occurs a note referring to certain water rights in the Bergen Ditch and Reservoir Company, The Harriman Reservoir and the High Line Ditch, which were excluded as not essential to the operation of the plant. They are strictly irrigation rights. The determination of value set forth on page 64 of Exhibit C. relates to Oct. 31, 1913. To bring it down to date we should add construction items since that date and deduct depreciation which has

occurred in the interval. The net difference would result in a deduction of from $50,000 to $55,000 bringing the net reproduction cost to date to a little less than $16,000,000. Considering every element affecting its value, such as its condition, its operating efficiency, and the service which it is performing and is capable of performing, it is my judgment that the fair value of this property for a rating base is $16,000,000. There are a few small parcels of real estate which are not directly necessary to the property except in so far as the maintenance of water rights is concerned. But the amounts involved are so small that it is my judgment that the sum of $16,000,000 may be taken as the fair rating base or the fair value of the property at this date. The engineers of the Public Utilities Commission concluded that the value of the property as of Oct. 31, 1913 exclusive of going concern value, water rights, and rights of carriage of water, was $10,044,778.31. The difference between our conclusions lies chiefly in the inclusion by us of the value of water rights, going concern value, certain property that was excluded by the board of engineers and in a somewhat greater estimate of reproduction cost on certain of the structures of the company.

370

Exhibit A. 21. is a summarized statement of the findings of the Public Utilities Commission engineers of the gross reproduction cost, assumed depreciation, and net physical value of the properties referred to, excluding water rights, going value and the right of water carriage, prepared by me from an analysis and study of their report. Exhibit A. 21 offered and admitted over objection by counsel for defense. The Master reserving the right to rule finally as to whether the report of the Utilities engineers is an admission against interest, binding the defendants, until such time as the evidence is all in.

Exhibit A. 22. is a comparison of the valuation of Metcalf and Anderson and of the engineers of the Utilities Commission upon the property of the D. U. W. Co. offered and admitted under the same conditions as Exhibit A. 21. Exhibit A. 23 is a similar comparison to exhibit A. 22 in greater detail. Exhibit A. 23 offered and admitted subject to the same objection and conditions as Exhibits A. 21 and A. 22. The note at the bottom of the Exhibit A. 23 calls attention to my belief that the engineers of the Utilities Commission deducted the valuation of the Harriman Reservoir twice.

Exhibit A. 24 is a summary of valuations upon the property of the D. U. W. Co. by the members of the former Board of Appraisers, Messrs. Freeman, Holman and Hazen, as of May 1, 1914, Metcalf and Anderson Oct. 31, 1913, and the Public Utilities Commission Engineer- as of Oct. 31, 1913. Also a statement of the securities outstanding and estimate of working capital necessary for the operation of the plant. Exhibit A. 24 offered and admitted subject to the same objection and conditions as the three previous exhibits. In item 8 Exhibit A. 24 referring to valuation by Public Utilities engineers is a note "partial valuation." I mean by that that there was excluded from their valuation, going concern value and water rights. Exhibit A. 25 is a concise summarized statement of the revenue and operating expenses of the D. U. W. Co. for the year 1913-1914 under the leaflet schedule and a computation to show

371

the results under the 20 per cent reduction provided by the rate fixing ordinance. On the basis of actual operating expenses with an allowance of $138,000 for depreciation and $30,000 for contingent reserve the rate of return under the ordinance rates would have been approximately 2.9 per cent on the valuation of $16,000,000. Also computations showing what the gross revenue would have to be in order to produce returns of 6, 7 and 8 per cent on a value of $16,-000,000. In order to give a rate of 6 per cent the gross revenue must be $1,634,000. 7 per cent, $1,794,000. 8 per cent $1,954,-000. or expressed in per cent rate of return upon net reproduction cost, 10 per cent, 11 2/10 per cent and 12 2/10 per cent respectively.

The significance of ascertaining the percentage of gross revenue to reproduction cost is merely as an aid to judgment. Within my experience the percentage of such gross revenue upon net reproduction cost for such property as this has run from 10 to 12 per cent. In my judgment the present gross revenue of the plant is too low.

Exhibit A. 25 offered and admitted. over objections by defendants counsel. Exceptions. Exhibit A. 26 gives in greater detail a comparison between the valuations by the Board of Appraisal, Messrs. Freeman, Holman, and Hazen, The Utilities Commission Engineers, and by Mr. Anderson and myself, referred to in summarized form in exhibit A. 24. Offered and admitted subject to the same objection and conditions as Exhibit A. 24.

Senator Patterson attempts to introduce the report by Engineers Phillips and Fellows made in 1910 on the value of the Water system of the D. U. W. Co. alleging that it is the report required by the charter amendment, therefore the report of the Utilities Engineers has no standing. The pamphlet was circulated during the bond issue campaign in 1910. Pages 62-64, pages 65-97, pages 105-107, pages 109-395, and exhibits, commencing on page 399 to the end of exhibit C, offered in evidence and admitted over objection of counsel for defense. Also pages 110-a and 110-b.

Cross-examination by Mr. Nye:

My first acquaintance with the property of the D. U. W. Co. began about Sept. 1, 1912. That was in connection with the adjudication proceedings for the water rights of lake Cheesman, in which I gave testimony relating to whether the use of lake Cheesman was a
372 necessary and beneficial use. I then examined the greater part of the property. My testimony then was based on the theory of the use of that water supply for the city of Denver so long at least as the city desired to use it for such purposes. I think it was recognized that the waters of the lake could be put to other uses, although I think that the direct question was whether the lake as now used in the service of the city was a beneficial use. My first connection with the valuation of the property began early in Oct. 1913. The inventory and valuation contained in Exhibit C. was for a dual purpose. We were first asked to assist in the preparation of such data as might be called for by the Public Utilities Engineers and second to supply a complete inventory and valuation for the benefit of the company for use in any possible negotiations with the city in

the future. The valuation then was considered more for the purpose of a possible sale to the city than for rating purposes.

There were no rating proceedings before the company at that time. I really do not know when the rating question first arose. Except for about four weeks I was in Denver constantly between the 1st of Oct. and the middle of February. I was not here when the rate ordinance was passed. There was some discussion in the press of the possibility of action by the council in reducing rates before my departure. In making an inventory of this sort we always aim to make it so that it may be used either for the purpose of rating or sale. I have participated in probably 5 or 6 rate making valuations and have participated in considerably more valuations for purchase purposes. There may be a substantial difference between purchase purposes and rate making purposes but not of necessity.

As I understand the law, in valuing for rate making purposes it contemplates a fair return upon the fair value of the property which may or may not be synonymous with investment. The Wisconsin Railway Commission recognizes that there may be a difference between value for purchase purposes and value for rate making purposes and in some cases has taken that into consideration. I recognize the rulings of that commission as one of the authorities. It is one of the ablest of our commissions. I do not think the California Commission is recognized to the same extent as the Wisconsin Commission. The New York Commission has had very little to do with water rates. In using Exhibit C. and the values there contained in this case we considered whether the properties valued were reasonably necessary to the operation of this plant for the furnishing of water to the city of Denver. The conclusion from this consideration differed very slightly from our conclusion for purchase, because
373 the amount of property that is not of immediate use in the service of the public is trifling.

To all intents and purposes the value for rating is the same as the value for purchase. The filtered water storage capacity of the system which is virtually the capacity of the distribution reservoirs within the city is 87,000,000 gallons. The average daily capacity of the filters and infiltration system is practically 68,000,000.

If the distributing reservoirs were full there would be approximately 87,000,000 gallons of storage in the city and the average daily supply available from the filters independent of the stored water would be 68,000,000. This average daily supply could be increased materially by operating certain portions of the plant at a higher rate than the average rate. Also, by drawing down the water level in the reservoirs. By drawing down the water levels substantially the water available throughout the conduits could be substantially increased, because they would be delivering their supply against a lower pressure. The question of the level at which water is distributed is controlled by the elevation of the water in the reservoir. Eliminating the supply from the three infiltration galleries, the supply from the sand filters and the mechanical filters can be increased above the present average. More water has been filtered through these filters for considerable periods of time than is shown by the

normal rated capacities without decreasing the efficiency. The sand filters cannot be forced to the same extent as the mechanical filters. The term approximate capacities used in connection with the tables of capacities in Exhibit C, is a general one and does not mean that the capacities cannot be accurately determined. The capacity of the filters is simply a question of the rate at which you run. The rate may be forced or may be decreased.

The average capacity of the Mississippi Street galleries is 7.3 million gallons daily but they have frequently supplied 13 million gallons daily. The water flows from the galleries by gravity and the flow is controlled by a valve on the pipe. By increasing the flow from the pipe the draft upon the galleries is increased. If less than the normal yield of the galleries is being drawn the water table automatically rises, if more than the normal yield of the gallery is being drawn the water table automatically lowers. I should estimate that the safe daily yield from the Mississippi Street galleries is probably 10 million gallons.

The tables at pages 34-35 Exhibit C. indicate that at times the draft on the Mississippi Street galleries has exceeded 13 million gallons. For the years 1900 to 1913 the average daily draft
374 from the Mississippi Street galleries is 5¾ million gallons. From Cherry Creek for the same period omitting the years 1906-7 when the conduit was out of service the average daily draft was 2½ million gallons, and for the same period the average daily draft from the Platte canon galleries is 6.2 million gallons. In my estimate forecasting water consumption I assume a considerable increase in the consumption in the next five years due to the increase in population. The water supply is available but the company lacks conduit capacity to take care of the maximum conditions which will then occur. This applies to the clear water conduits, the raw water conduits are of sufficient capacity to materially increase the supply if means are provided to take the filtered water away from the plant. As a guess I should say this maximum demand may require an increase of 25 per cent in the clear water conduit capacity. The infiltration galleries, except the Mississippi street galleries are now operated up to their normal capacity. In the Mississippi Street galleries there is a margin of 4 or 5 million gallons a day.

Our net reproduction cost of conduit No. 6 exclusive of lands and rights of way and exclusive of No. 6 extension was approximately $353,000. The extension runs from Wynetka to the Marston Lake Reservoir. The capacity of the conduit is approximately 23,000,000 gallons. If the 48 inch branch of the 60 inch conduit is shut off the 36 inch branch will carry a greater proportion of the supply from the 60 inch line than it will with the 48 inch line open. The 36 inch branch of the 60 inch conduit to the Platte Canon Reservoir has a greater carrying capacity than the 48 inch branch to Marston Lake because of the difference in the length of the lines and the frictional loss.

The total value of the abandoned property of the system is approximately $1,261,000. Information as to the length and size of wood and cast iron pipe abandoned was obtained partly from com-

pany records and partly from employees. The weights applied to the cast iron pipe are the same weights that were used in our reproduction cost estimates. We took into consideration that in the early stages of the existence of these works some of the pipes were, I believe, of lighter weight than class B. and we made an effort to estimate the average weight of the system as a whole. I am not clear in my recollection as to whether that was pipe laid by the Citizens Water Company or some other company.

I am not able to say what portion of the lighter weight pipe put in by any of the companies is included in the abandoned property.

We included the Sullivan Reservoir in our total valuation.
375 The net value allowed was $132,000. If it is classed as abandoned property it would increase the abandoned property estimate $1,261,000, by the amount of its gross reproduction cost, something like $190,000. Sullivan reservoir has never been used or connected with the system. Water from the Cherry Creek galleries could not be used through Sullivan Reservoir except by pumping. It could not be supplied from either Platte Canon or Marston Lake without pumping. I do not know what office the reservoir was originally designed to perform. It could be utilized as a high service distribution reservoir by pumping water to it from the University Park Station or any convenient point where coal could be obtained on the railroad sidetrack. I understand it was constructed prior to the organization of this company.

It seems to me that it is fair to include it in the valuation for rating purposes at this time, because the company has actually under contemplation plans for its use, which would be advantageous. The column marked "pressure range and pounds" at page 105 of Exhibit C is not filled out simply because there were so many different systems in use here that it could not be well put in so small a space in an intelligible manner. The quotations from the Underwriters report and the accompanying tabulations and diagrams take the place of that item. Neither Mr. Anderson nor myself made tests of the pressure as the Underwriters did, but we made a study of existing records and results obtained.

Bonds of the D. U. W. Co. to the amount of $8,000,000 are outstanding and bonds of the S. P. C. & R. Co. to the amount of $4,000,000. It is my impression that $880,000 of the bonds of the S. P. C. & R. Co. are owned by the D. U. W. Co. I took into consideration in determining the value of the property, its outstanding securities. I did not consider their market value because it seems to me to be without significance under the conditions here existing, which I certainly consider abnormal. I considered the income of the company from making new taps as an item of revenue. In its bookkeeping the company handles it as an offset to operating expenses. I included in the value of the property a valuation for the service connections though I knew that they were paid for by the consumers. I regarded the taps in the nature of a betterment which could not be removed from the system. I have also given the city credit in the consideration of revenue for the profit derived from their construction. Also, the charge made for them may well be considered in the nature of a license charge to the house owner for

the privilege of connecting with the mains. Part of the value assigned is a value because of the fact that the connection is
376 there and through it the company is enabled to deliver water and to earn a return.

It is true that the net reproduction cost allowed for the connections is considerably greater than the profit derived by the company from making them. As I see it this value is not a value which should be included in the going concern value. I do not believe that I have duplicated it by allowing for it in both reproduction cost and going concern value. It is not in the going concern value. I have not included in the valuation the service pipes attached to the tap. Have not been able to ascertain accurately what amount of class A pipe laid in the system but on the assumption that all of the Citizens Pipe now remaining in service was of that class it would not make a difference of more than $10,000 in the value of the system.

I think we took that into consideration and made liberal allowance for it by eliminating the excess weight allowance always provided for in the specifications for pipe contracts. The existence of class A pipe would not affect the pressures, on the system within the limits of pressure that exist in this city. I have found no evidence to lead me to believe that electrolytic action would have any affect upon the lighter weight pipes. I think the precautions taken by the company to protect its pipes against electrolytic action are reasonable and proper. I made no examination to determine the condition of the pipe because that is practically impossible, but I did discuss the matter with Mr. Thomas and the foreman. The pipes were bonded to the rails some seven or eight years ago. But even before the bonding the electrolytic action was limited chiefly to certain service pipes in proximity to the power stations.

No doubt it has been known to the designer of the pipe system that the city maintained a fire engine service for the extinguishment of fires and that as well as financial consideration had a bearing upon the size of pipe adopted for different streets. It is clear that if the service will not produce a reasonable return on a large pipe and reasonably adequate service can be furnished through a smaller pipe, that the smaller pipe will be laid. The water company would have no objection to laying larger pipes than it does provided a return commensurate with the increased cost of construction could be earned. In making that statement I have in mind the number of consumers on a particular piece of pipe and the return enjoyed from hydrant rental, rather than the rate which any particular consumer would pay.

I think that water works construction always contemplates the use of pressure from the system for fighting fires and many
377 fires are put out without the use of the steamer. The situation here is such that a system entirely a gravity system with an adequate pressure for fire protection could be installed but at increased cost. I doubt if it would be financially worth the price. The water from the Mississippi street galleries is slightly harder than the other water. But mixing that as they do with the other water it does not seem to me that it is a matter of serious import. If a condition arose that might make it advisable to discontinue the

Mississippi Street supply, the deficiency in supply thus created could be made up from Platte Canon or Marston Lake by an increase in filter and clear water conduit construction.

Hypochlorite is simply inimical to bacterial life. Its function is entirely different than alum, which is a coagulant. You could not raise the efficiency of the mechanical filters substantially by the use of additional sedimentation before application to the filter plant. You might increase the capacity slightly but not materially. I stated that there undoubtedly were some instances where at or near the top of some of the services the water pressure was not all that could be desired. This condition is worse during the hours of irrigation. It is my judgment that the use of meters would be the most effective remedy. There are meters of modern construction which are efficient and comparatively cheap to install. I stated that the general condition of the pipes, conduits, reservoirs and storage basins was excellent. We made some examinations of the wood pipe conduits, by excavation and inspection of the external conditions and the internal conditions where we were able to see the pipe. I was not here when the conduits were broken by the floods. I arrived here just after, went up to see the openings and saw some of the staves that were taken out, those I saw were in very fair condition. The conduits were covered with water so I was unable to make any extended investigation of them. The excavations that we made by the inspection of the conduits were the same as those made under the direction of the Public Utilities Commission engineers. I did not personally see all of them. Some were seen by Mr. Barnes, some by Mr. Anderson. Mr. Skouland reported to me on some of them and Mr. Thomas told me more or less about them. I also saw several of the pipes on the occasion of my previous visit and I have seen two or three openings since I came back. I also know the delivery capacity and have had conferences with Mr. Hazen and others in regard to what they observed when they were here. There are a few points on the system at which the pipe has not at all times run full most of which have been replaced by pipe of cast iron or other material. The capacity of the Mississippi street conduit is
378 about 13 million gallons daily. The fact that it is normally operated at about 6 or 7 million gallons does not mean that the pipe is not running full.

It is my impression that the pipe is controlled at the lower end so that it would be full regardless of the quantity carried unless it drew the ground water level down below the top of the pipe. In valuing the Archer Lake lands we took the value arrived at by the real estate experts and not the right of way value fixed by the railroad man. In finding the value of the lands we excluded from them the value of the water rights simply as a method of finding the combined value. We treated the water rights separately from the lands. I think that is common practice with most engineers in such work. We are facing the same situation of combined land and water values in San Francisco. Mr. Anderson and I are working together there and working on the same basis as here. I don't know that I can cite specific instances but there is no question in my mind but water and land values are generally segregated by engineers. In water

power diversion cases it has been very common practice in the East to separate the two. There have been very few rating cases in water works litigation up to date. There have been many condemnation cases but very few rating. I think the San Joaquin valley case recently decided by the United States Supreme court and the San Diego case are cases where land and water values were segregated. Some of those cases have been decided since we made this finding. I do not think the method was either mine or Mr. Anderson's or a composite. I think it has been used for many years and there is nothing novel about it. Drawing the full capacity of the Mississippi Street conduit would not necessarily mean that the water level would be lowered below the top of the pipe. Of course, that would depend upon the height at which the water table would stand, but it is my impression that the gallery is low enough so that would not occur. I would be glad to ascertain for you if you wish me to do so. The greatest life may be expected of these wood pipes where the interior of the pipe is constantly in contact with the water surface. Rotting occurs where it is alternately exposed and covered with water. Soil conditions also affect the life of the pipe. I could not say which would be the most effected the pipe or the bands. One stave in the periphery of the pipe might give way and be replaced without necessitating replacement of the rest of the pipe or of the bands. Though if some of the bands were badly pitted they would be replaced.

I testified that we allowed a valuation of $200,000 for the Lake Cheesman land which would be equivalent to a valuation of $200 an acre for the submerged land and to approximately the
379 cost of the lands above the water level. In a general way we assigned those separate values. That would be equivalent to about $3 or $4 an acre for the lands above the water line. In assigning those values to the submerged land I do not think we distinguished between the value for a reservoir use for irrigation purposes and the use for domestic purposes. Whatever difference might exist between the value for irrigation purposes and the higher use for domestic purposes I should be inclined to throw into the water rights rather than into the land values. I am inclined to think that the lake is more valuable for domestic purposes than for irrigation.

I think the portion of the value assigned to the Lake Cheesman water rights was about $2,000,000. Mr. Anderson worked it up in detail and I reviewed it with him. In the light of my experience elsewhere it seemed to me that the results which he found was a fair one and I therefore accepted it. We debated a number of points in connection with it but that does not signify that I had any lack of confidence in his judgment. We added in the case of the other land to the value found by the real estate experts, ten per cent to cover engineering, legal and contingent expenses, incidental to bringing the lands together, making plans, surveys, etc., such expenses as in my judgment are generally incurred in purchasing lands for such uses. That is a part of reproduction cost. And it is not an element included in going concern value. The value is not duplicated. That ten per cent is not an operating expense.

271

A considerable portion of the construction since 1908 is what may be denominated piece meal construction, though some of it is in large enough units so I don't think that can be said. This construction since 1908 has not been carried on without increase in the overhead expenses of the company. I did not add 12½ per cent to the cost of this construction in my estimate. All of this work was included in my estimate of the reproduction cost of the entire system.

My unit prices on the whole works were somewhat higher than the unit prices for the distribution system work since 1908, because most of that work was done in the outlying districts and though of piece meal construction, was substantially less difficult than the work would be taking the system as a whole. The annual depreciation estimate at page 65 forms the basis of determination of the accrued depreciation as well as the basis for determining the depreciation allowance for the future. In carrying depreciation allowance forward for the future as in Exhibit A.25 the allowance for the year 1914 is increased above the allowance for the year 1913, on the theory that increased demand on the plant requires increased construction, increased construction develops increased depreciation. Therefore, that increased allowance must be made from year to year. My reason for the additional allowance of $30,000 for contingent reserve is to provide an element of safety to take care of unfor-seen conditions, such as bad floods, cloud bursts, etc., which would result in extraordinary expense. To include those in the operating expenses of the year would make very heavy inroads upon the net revenues. If it were extreme it would affect the market rates at which the company could obtain capital. You may have a bad accident from electrolysis which would involve thousands of dollars of damage as has happened time and again in our American cities. Rather than absorb that in one year in operating expenses it is more prudent to make an additional allowance such as this and distribute it over a period of years.

380

This fund if not called upon would be a gradually accumulating fund. If it became substantial in amount you could cut it off entirely or reduce the annual allowance. It has generally been found in the operation of public service corporations that it is well to have such a surplus which can be drawn upon when emergencies come. Take the situation with the Tramway Company last winter in the extraordinary snow storm, and the extraordinary expenses growing out of it. To take care of that from the revenues of one year is a disturbing influence. To take care of it in part out of a fund which has been accumulated for a period of years tends toward the stability of the credit of the corporation. I do not wish to imply that the adoption of the figure, $271,094 the average value found by the real estate men for the Lake Archer lands is the exact economic point at which those lands might be retained in the system. We did not attempt to figure the point at which it would be economical to sell those lands. We adopted that figure as more fair for the rating base than the higher figures testified to. I took into consideration the expense attendant upon the furnishing of the water

supply through the West Denver station by comparison with the other supplies. As it is operated, the cost of water from that source is greater than from the other sources, but from the point of view of the available quantity from that source 10 million gallons daily, the cost is practically the same as from the other sources. I regard the difference in cost as more than offset by the increased safety which comes from having that quantity of water available nearer the city where it can be quickly reached. Assuming the use of such a valuation as $600,000 for those lands, fixed by Mr. Young, my conclusion as to the economy of that source would be different. If the company could realize that sum of money for those lands it would be wiser to give it up as a source of supply. The water power
pumps at West Denver operated by the water developed
381 through Lake Archer have during the period, concerning
which I made investigation, 5 or 10 years, I am not certain which, furnished about 1/3 of the supply from that station. The West Denver station is fully equipped to pump all of the water it furnishes by steam, but nevertheless there is a saving to the company in pumping part of that supply by water power. I cannot answer as to whether that saving is commensurate with a fair return upon the value upon that portion of the property known as the Lake Archer land. There are a good many questions involved in that. It is possible that a necessity for the continuation of the water rights is involved.

It is possible that if it can be disposed of for $600,000 or more there would be an economic waste in maintaining it for its present use. I dislike to say definitely without knowing all of the elements of my problem. I referred to the item of abandoned property simply as giving the measure of the total depreciation which the investment here has suffered. It was not included in the reproduction value. Except as it sheds a side light on what is a fair allowance for depreciation it has no connection with present values. It is an element to be considered in connection with original cost.

The original cost of this property cannot be determined. The records do not exist. There is no single element that is always of controlling importance in the ascertainment of present value. Original cost particularly in a young plant is an important element if you can find it. The older the plant is the less of a measure will the original cost be under present legal conditions. In determining unit prices on the distribution pipe system we considered both the prices of labor and material prevailing during a period of years. I think today looking forward for a period of 5 years we are facing a rising rather than a falling market. That element caused us to consider the average for the preceding 10 years as a proper figure for present reproduction cost. If the coming 10 years should have a downward tendency the unit bases would not be correct. But we cannot go much lower than we have gone without putting pipe foundries out of business unless some entirely new process is developed to enable them to make pipe at a very much lower figure. We took into consideration the prevailing price in formulating our estimate.

Allowance for paving over mains was made on the theory that whether the mains were there or not when the paving was laid a reproduction of the system as it now exists would necessitate the tearing up and relaying of the pavements. I believe also that the plant is more valuable from the viewpoint of the stability of the investment with pavements than without. Expenses of operation and maintenance also are greater with pavement than without. Those elements are to be considered in rating as well as in purchase cases, as I see it. The difference in the cost of excavation for three, four and six inch pipes, though the trench is the same width, results from the difference in depth. The cover over the pipe being the same. In determining the reproduction cost we took into consideration the fact that if one were actually reproducing this system some of the pipes lying under or adjacent to street railway tracks would not be laid in that position and made what in our judgment was a proper allowance for the conditions which exist. I had reached the conclusion as to the fair value of this property prior to the passage of the ordinance in question in this litigation. Those figures did not differ materially from the figures concerning which I have now testified. That determination was based principally upon investigations made by myself or my assistants. In making our comparisons of physical valuations with the figures of the Utilities Commission engineers we eliminated the $375,000 allowed by them for development expense.

382

I understood that the Utilities Commission engineers did not allow any value for water rights. If it is true that their land values contained any allowance for water rights then the tables of comparison should be reconstructed to exclude from consideration the real estate and make the comparison on structural items only for the final comparison. As a matter of fact the comparisons are made separately in my tables so the items can be easily segregated.

The item of $144,000 depreciation allowance for the year 1914 is an estimate. This is true of all figures presented carrying forward from Oct. 31, 1913, data bearing upon the plant. In table A22 the absence of figures in the column headed Public Utilities Engineers and opposite the item, going concern value and water rights does not imply that the engineers did not give consideration to them but merely that they did not place values upon them, other than you may consider the development expense of $375,628 as a substitute for going concern value.

It is my understanding that they did consider both these items but placed no value on going concern except as the development expense item may be applied to it, or upon water rights other than for irrigation purposes incidental to their use upon certain lands which appears in the land values. I understand that the Public Utilities engineers did recognize certain water rights and included a value for them in the lands outside of the city. To that extent the figures dealing with their net physical valuation included such value as they assigned to those water rights. In exhibit A19 in the computation of development expense I started in 1895 with an assumed capital investment of $7,000,000 represented by the bonds outstanding, after determining the net revenue and the

383

fair return at 7 per cent plus 1 per cent for depreciation. I took the difference between the actual net revenue of that year and the estimated fair returns and showed that as a revenue deficit for the year. This deficit I added to capital account for the year 1896 for the purpose of the computation for that year. The same method is carried through the whole table. That method of computing development expense is used by the Wisconsin Railway Commission. The second table is the same with minor corrections in the net revenue. The third and fourth tables include the addition to capital account of items of construction actually made. And the fourth table is computed on one per cent less rate of earnings than the third. I think the deficits should carry compound interest for the reason that in a computation to determine development expense you consider the deficits as an investment. The owner being entitled to a certain annual return. Had he gotten his return he would have enjoyed interest upon it. And interest again the following year upon the previous interest account. So as an investment he would have enjoyed in fact, compound interest. Compounding the deficit in this computation carries it forward in precisely that manner. If the investor 20 years ago lost a certain sum of money in interest payments he has today lost not only that sum of money but the compound interest upon it which he would have enjoyed had that sum of money been paid over to him 20 years ago.

In this computation the question of bond issues is not considered at all. The rate of return is considered as necessary to produce so much net revenue. It does not matter how that net revenue is disposed of, whether it is paid out as interest on certain bonds or whether it is paid in dividends or some other disbursement made.

The moneys paid out for lease rights are considered as operating expenses except the payments on account of the lease of the D. U. W. Co. from the S. P. C. & R. Co. which is not taken into consideration at all. I have made no separation between the properties of the company. Rentals on the other leases are paid to outside interests. In the matter of the rental paid for the use of the city's mains I have treated that as in the case of rental on other property, as an operating expense, and have considered in these computations only the actual revenues derived and the rentals paid. I do not consider that the company is occupying the streets without compensation to the city. It is rendering the city service and is furnishing free water to the city for various purposes to a substantial amount.

384 In the computation at page 13, Exhibit C, dealing with the question of safe yield of the various water sources, I have considered as the safe yield, the amount that could be derived safely in dry years. In the table headed "Safe yield of water sources for irrigation purposes" the quantities there set forth are the estimated quantities for 365 days in the year. The safe yield for domestic purposes would be somewhat less than that. You would get that quantity under average conditions but not in the driest year. The quantities stated may be regarded as the yield for domestic purposes under average conditions but not the safe yield because we use the term safe yield in application to dry weather conditions.

Not to the average conditions that prevail upon the water shed. In irrigation practice you assume more nearly average conditions.

The words, "Yield for domestic purposes in the average year" would mean substantially the same thing in the heading. I will have to refer you to Mr. Anderson for details as to the valuation of different water rights.

Essentially the responsibility of fixing the values of water rights rests upon Mr. Anderson though I went over the unit figures with him and the final results merely to satisfy myself that the results arrived at appeared reasonable, that I might incorporate them in my valuation. As to the value of lands covered by reservoirs or other works, they were arrived at by joint consideration. The additional value allowed for such lands was by reason of their availability for the purpose, rather than by reason of the use to which they are put. Generally the criterion has been the reproduction cost of those lands based essentially upon present market value together with allowances for the cost of assembling these tracts for these purposes. We gave consideration to the existence or non-existence of other lands available for the same purposes, for instance, it was considered that the Platte Canon Reservoir site was less valuable by reason of the fact that other sites could be obtained near by, than the Marston Lake site or the Cheesman site. These valuations were arrived at substantially without consideration of the fact that the reservoirs are used in connection with a domestic water supply. I cannot say absolutely without, because in the case of Marston Lake its advantageous proximity to the city was considered.

I did not consider in arriving at the value of these reservoir lands that they are used and useful in earning a return from the supplying of water to the City of Denver. Exhibit A22 shows the land values to be $1,014,000. Page 64 of exhibit C. shows the land value $920,103. The difference is due to the fact that in Exhibit A22 interest during construction has been added. From the tables in Exhibit C. the use of water by the city of Denver in cubic feet
385 per second can easily be determined by applying the proper factor to the acre feet or million gallons set forth in the table. I know of no figures that would show the average use by the company of water for irrigation of lands or the acreage irrigated. The safe yield of all of the water sources for domestic purposes, taking into consideration the driest conditions of the driest years would be from 140 to 155 cubic feet per second.

No strict line can be drawn between repair account and depreciation account. It is good judgment however in the operation of public utilities to charge liberally into the repair account rather than depreciation. Expenditures for repairs are not an offset to depreciation nor is ordinary maintenance. Certainly the depreciation allowances which we have made in this case do not contemplate the charging to them of ordinary maintenance and repairs. I used the sinking fund method as one of the methods in ascertaining the going concern value assigned here, also in determining the allowance for annual depreciation, that coupled with judgment. I stated that I made no allowance for salvage value of the items at the end of their term

of useful life. Allowance for annual depreciation is really an annuity which at a certain percentage will amortize the property at the end of a fixed period. I assumed the period of the useful life of each particular item. The results that I have obtained here are practically the same as if I had used the straight line method. As indicated by the past experience of this company, under the straight line method it would have required an allowance of approximately one per cent per annum on the structural values. Or in other words, $130,000 to $140,000 per annum. The additional allowance of $30,000 per annum for extraordinary contingencies is based upon the past experience of the company in so far as the contingencies do materialize but not as to the making of the allowance. That experience indicates a necessity for such allowance if the fair average rate of return is to be enjoyed by the corporation. The past history of the company does not indicate that it has been required to spend that sum each year for such contingencies because the value of the property going back over a period of years has been much smaller than it is now, in other words, if $30,000 is fair today it would not have been fair ten years ago or would it be fair ten years hence.

Experience in the future may prove that the allowance that I have made of $30,000 is too large. It is true that in a purchase case or for purchase purposes value is largely what may be denominated an exchange value, largely dependent upon the earning capacity of the property. In a rate case the question is what the earnings shall be. It is true also that in determining my valuation here I have assigned a value to water rights largely in excess
386 of their original cost. It is partially true that the computations of going concern value are based upon the return under rates in effect here predicated upon the assumed value of water rights. But I have also figured going concern value upon an assumed rate of return entirely independent of the actual rate of return obtained here and it is my judgment that the going value or development expense that I have found is substantially less than the actual expense to this company to build up its business.

Exhibit A19 indicates ten different results of computations of going value or development expense with results varying from $990,000 to as high as $5,750,000. It is not true that going value or development expense can be estimated or figured at almost anything that the individual who is doing the figuring wants to. It certainly is not true if the individual doing the figuring is intellectually honest. I do not believe that anyone who is intellectually honest would be guided in the least by any preconceived idea of what should be allowed for going value. The final decision as to going value or development expense is a matter of judgment as is the case with almost everything in the matter of valuation. I took into consideration in arriving at both the going value and the general value the fact that the company's franchise had expired.

I do not believe that public service plants operating under franchises have been operated with any such disaster in view as the scrapping of the plant at the expiration of the franchise period. I do not think that the rates have been based upon any such assumption

or that the returns enjoyed would make it equitable to apply any such drastic rule. I believe that if it was fairly to be assumed that the city shall proceed to duplicate this plant within the next five years that it would be equitable for this company to increase its rates to liquidate the loss in value which will occur in the next five years during the period of construction by the city of its new plant.

The company's franchise is gone, it has no further rights in the streets, it may be ordered out of the streets, but the rates charged have not been such as to enable it during its life to liquidate its entire property excepting its scrap value. Then according to my view it is as reasonable, just and fair to the public that that loss in value should be liquidated in the next five years as prior thereto. It has not been common experience in this country that cities would take such action as would lead to the wiping out of property values to such an extent as is implied by your question.

It made no difference to the company as I see it whether the city undertook its construction operations before or after the end of the franchise. Had the city elected to notify the company five
387 years before the expiration of its franchise that its plant would have to be scrapped at its termination, the company then would have made provisions in the remaining five years, just as I believe it should make provision in the coming five years if the plant is to be scrapped. I assigned a value to the connections to the company system notwithstanding that those connections were paid for by the consumers. The gross amount on page 64 of Exhibit C. is $157,543 the net amount $126,034. I considered that as a betterment of the plant that could not be removed. Just as the tenant of a building may put in a furnace, steam heating or lighting plant, and though he has paid the cost of it, it remains the property of the owner of the building. I have considered that the corporation cocks could not be removed, even though the owners service was reconnected to some other pipe system. The service pipe could be removed but not the corporation cock.

Those elements are no more to be considered in a purchase case than in a rate case, if it is a fact that the rates shall be predicated upon the fair value of the property. The property of the company is more valuable by the reason of the service connection whoever paid for it. If the rates shall be predicated upon value which has become inseparable from the plant it seems to me that there is no difference between the two. If it be true that the profits of the company from the installation of consumers' service connections figured at four per cent will today amount to over $100,000, I have given the city credit for those profits in discussing the return which the company has enjoyed. I have also charged to the company that profit in the consideration of development expense. Because if you deducted the profit actually enjoyed from making these connections you would have increased the annual deficit in the operation of the company which make up development expense by just that amount. The method that I have used in determining the question of deficits I think is a proper method.

Cross-examination by Mr. Patterson:

I do not know anything about the bonds of the S. P. C. & R. Co. owned by the D. U. W. Co. I have not considered securities in determining the value of the property. In my judgment the allowances for engineering and contingencies, interest during construction, preliminary expense, etc., are not heavy allowances. I know that the Wisconsin Commission combines engineering, superintendence, legal expense, interest during construction, and contingencies, and has not allowed more than 12 per cent for the aggregate of those items. I also know that the plants which it has valued are very different. I do not believe that this is an undeviating rule or that the commission has an undeviating rule. I do not know
388 whether the D. U. W. Co. at the time of its organization paid to the companies whose property it acquired the full value of that property. The companies had been having a rate warfare and whether either was at a disadvantage at the time of purchase, so that it received less than a fair value of its property, I do not know. I have not attempted to make a division of the items of engineering and contingencies. Engineering costs would probably range from 6 to 8 per cent. You can reduce the engineering to four or five per cent and make mistakes which will cost you the difference.

The Wisconsin Commission may fix it at 4 per cent but engineering work cannot be done at four per cent. I think it would be from 6 to 7 per cent on such a plant as this. I presume my present connection with the D. U. W. Co. is as consulting engineer. My first connection with the company in connection with this litigation began early in Oct. last. I was here before in 1912. At that time I appeared before the Master in a hearing at Hartzel and gave testimony upon subjects upon which I had information. I was here on that occasion about 2 weeks. The D. U. W. Co. employs a very competent corps of engineers. Mr. Thomas is chief engineer, Mr. Anderson has been employed as consulting engineer from time to time. I do not think that he has been on a continuous retainer at any time. All of the expenses of the regular engineering corps of the company are not included in regular operating expenses, part of them are charged to construction according to the amount of construction that is being carried on. I have not charged 12½ per cent engineering to the cost of this plant in addition to the expense of the company's engineering department. There is no connection between my 12½ per cent allowance and the charges made to the construction account by the company. You are confusing the original cost with my reproduction cost. We used the company's construction costs where we could get them as an aid to judgment. We gave great weight to the original contract and original cost at Lake Cheesman. There are a great many items in the construction account on which we received no aid from the records of the company. Generally the construction cost could not be segregated from the records of the company to apply to every item of property. It was only in cases where the construction cost segregation was sufficiently complete to clearly identify the property and in which the construction was

recent enough to make figures significant that they were an aid in forming judgment. We got in the aggregate what were reported as the construction costs of different parts of the plant since 1895. These aggregate figures were not segregated so as to make it possible to determine to what items they applied. It is not safe to assume
389 that the total expenditures for hundreds and thousands of items all lumped together on construction account are a safe criterion of present value. I did not proceed as you infer. I did not supply omissions in the accounts. The fact that these items are not segregated on the books is the fault of the bookkeeping custom that applies the country over. If it be presupposed that the corporation should keep a complete record of all construction items and quantities, abandoned structures, etc., a complete detailed record of the segregation of costs, then it is true that we did not find such detail here and it was the fault of the company, if that is your premise. It is not true that as your question implies my valuation was built up from an assumed amount in 1895 of $7,000,000 plus the construction costs of this company. Those figures were taken from the figures of the Public Utilities Commission engineers and used simply in a computation showing one method of arriving at going value. I used those figures in order to determine the difference between the actual rate of return to the company during that period of years and an assumed fair rate of return of 7 per cent plus 1 per cent for depreciation. I am unable to say whether the construction account used for the purpose of this computation contained engineering expenses, except as related to the construction items in the last five years on piping, there it did include such an allowance. Whether every account contained its just share of engineering I do not know and no man can tell. I have made no direct use of the construction costs as they appear on the books of the company in determining the value of this property. I have used them as an aid to judgment. Where engineering costs appeared in the construction record we eliminated them and used the basic cost without any such allowance. In the particular cases as I remember them the engineering charges were greater than the allowance which I made. I undertook to find out what the actual engineering cost had been and found it impossible to ascertain that from the records of the company. I made an allowance for paving parking and railroad crossings on the theory that that cost would be incurred in reproducing the system. In ascertaining the reproduction I mean that I estimated the cost which would be involved in reproducing the plant as of the date of application.

In order to value the property I do not actually lay the pipe. Theoretically you are constructing a new plant, practically similar to the one being inquired about and giving the cost of the construction. I am a member of a committee of the American Society of Civil Engineers to formulate principles and methods for the valuation of public utilities properties. The outline of that report was read at the January meeting of the society but it is very far from what
it will be in its final form. The report states in part: "The
390 principles and methods involved are now being carefully considered by many public service commissions and the

courts, as well as by engineers, lawyers, and various societies having to do with public utilities, the subject is clearly in a developmental stage and any conclusions reached at the present time must be considered as tentative." In the third paragraph on page 6 appears: "It is obvious that a valuation for use before a court or public service commission must, in order to be sustained, be made in conformity with existing laws and the decisions of higher courts."

"It is recognized however that the whole subject is in a developmental stage and while your committee has been guided largely by the decisions of the higher courts and public service commissions it recommends what seem to be sound views and desirable changes in practice, even though not wholly in accord with such decisions." It has been well settled by the highest courts that the owner of such property is entitled to a fair return upon the fair value of the property utilized in or necessary to the service. Justice and equity alike require that in any regulation of rates there shall be taken into consideration, two distinct features, 1st, the annual return covering interest and profit to which the corporation is entitled for the use of its capital, having in view the risks incidental to the investment. 2nd, An allowance sufficient to provide for the net depreciation in the value of the items of physical property whether resulting from decay, wear and tear or other cause, the amount of such depreciation allowance to be sufficient to amortize all such items of property by the time they cease to have value.

"Public policy requires that in the absence of any plan for public ownership of public service property the earning capacity of such properties may be made sufficiently attractive to induce capital to provide the works needed for the public welfare and convenience,—to maintain them in proper condition for providing good service and to extend them reasonably in advance of the needs of the community. The public may be as injuriously affected by too low as by too high rates."

"If the public regulation of rates to be charged by public service corporations is to become general the fairness and uniformity of methods of valuation for rate making will have an important influence upon the supply of capital for such enterprises, and upon their maintenance and development so that they will furnish satisfactory service to the public."

"As already indicated no complete and definite rules have been laid down for the determination of the fair value of a public service property. The matter is so difficult that courts and commissions have in the majority of cases stated that they have given weight to valuations determined by several different methods and that after due consideration have reached a certain conclusion which
391 they announce without disclosing definitely the method by which the conclusions have been reached. This appears to have been a wise course to pursue during the developmental stage of this subject, in view of the weight as a precedent given to important court decisions."

The committee tried to perform a dual function which was dangerous as subsequent discussion has made very clear, for we have been

found fault with by a great many lawyers and engineers. Fundamentally the question at issue is this: Shall investment cost in the property be the proper criterion of value or shall the fair value of the property including increment in value which has come with the lapse of time be the criterion? It becomes then a question of administration. I think that no member of our committee felt that the actions which we have outlined here could be made retroactive.

Our report as I see it is in substance this: And this it seems to me is the important thing which you have absolutely overlooked. Under constant and long time commission control it was the view of the committee that the rating base would come more and more nearly to approach the investment cost, rather than present value or reproduction cost. The report as originally drawn referred not to investment cost as it does today but to reproduction cost as the criterion of value. It was then held by a very strong member of the committee who has since died, that under public service commission control, and constant commission control,—I do not mean to imply a commission control which has come in for one or two years—investment cost, the fair investment cost of the property would become the basis of rating. It was the view of the members of the committee that in the case of recently constructed properties,—the investment cost was the best evidence of reproduction cost, and that, therefore, as applied to recently-built properties the terms "investment cost" and "reproduction cost" were practically synonymous, except in such cases as there might have been injudicious expenditure. As you get further and further away from recent construction, it was the view of the committee that investment cost could not be used as the basic criterion of value. In other words, the report of the committee, as I see it and as I saw it when I signed it, sir, relates to a condition of affairs under public service commission control, extending over a period of years,—rather what we are tending toward, as we believe, than what lies behind us in the decisions of the Courts.

When you come, however, to make a valuation of a property, as I have made in this case, I conceive it to be my duty to follow the precedents laid down by the Courts, as I see them, rather than what I believe will be the future tendencies.

392 Now, as bearing upon the utilization of the investment cost under constant public service commission control, rather than the reproduction cost, it was the view of every member of that committee, sir, that the rate of return upon such a base would inevitably have to be increased over the present rate of return, as measured by the fair value of the property, if capital was to be obtained by the corporations for future extension of the works. Now, if you adopt, the theory that investment cost shall prevail hereafter under continuous public service commission control, future extensions will be made in the light of that assumption and that will become, in effect, the book cost of the property, watched over by your public service commission.

It is my own sound judgment, Senator Patterson, that the point of view of the readers of this report has been so totally different that the report, as it stands, is not a safe document to go out, and I be-

lieve that those matters to which I have just referred, and others will be made clear in the report of the committee finally adopted, if it is possible to adopt such a report. Now, if it is—if we come to the basis of investment cost hereafter as the criterion of value, and take into consideration the other elements through the rate which we fix which shall be enjoyed upon that base, the rate, as I said, will be, in my judgment, increased. If you adopt that basis, then the original conditions of construction must, of course, logically prevail, as outlined in the paragraph which you quoted, sir. If it is true, however, as I believe it to be true, under the present—the past decisions of the Courts, as I read them—that reproduction cost shall be on the whole, or is on the whole, of the greatest importance, then I submit and I have so interpreted the law always, that the present conditions shall prevail. In other words, the plant shall be reproduced under conditions prevailing as of the date of valuation. That is the essential difference in the two points of view."

After the general statements in the report, specific questions and matters are taken up under different subheads, always under the one central theory, that it treats of investment cost under continuous public service control rather than present fair value. It is desirable to determine the actual cost of structures recently built, we always try to do that.

To take a single paragraph out of the report as you have been doing is in my judgment to present a garbled version of the report.

(Argument between Mr. Patterson and the witness as to the effect of authorities in cases involving allowance for pavement over mains. Finally stopped by the Master on the ground that that was a question for the court to decide.) The net allowance by us for the
393 item of corporation cocks was $126,034. If the service pipes were the property of the company, by reason of ownership, then of course I should include them in the rating base. As a matter of fact I have excluded the service pipes in this city drawing the line at the corporation cock, which cannot be removed, which is inseparable from the pipe system. The service pipes can be removed without injury to the pipe system. The principle of reproduction cost as applied today is determined by present conditions of the property. For the purpose of such inquiry the conditions existing at the time of original construction have very little to do with the case. Under the reproduction cost theory you attempt to determine the reproduction cost of the plant as it is today.

We allowed for the lands at Lake Cheesman the sum of $200,000 divided approximately on the basis of $200 an acre for the submerged land and $3 or $4 an acre for the remainder. I ascertained what the cost of the 8436 acres was. The cost to the company of the land under water was not segregated. My assumptions and distribution have nothing to do with original cost.

(Restatement of reasons for employment by the D. U. W. Co.)

Part of my duty was to prepare data for the engineers of the Public Utilities Commission. I had a few interviews with the commission engineers. We may have discussed matters that should be included in the valuation of the property. I had some corre-

spondence with the commission bearing upon omissions and errors in their report and at the request of Mr. Van Diest I prepared some data on decisions and valuation cases for rating and other purposes. We may have discussed the question of pavements but I have no distinct recollection about it. I understand by going value that element of value in the property growing out of the established business, or the difference between its value without any business attached to it and enjoying no revenue and its value with the attached business and revenue.

There are two general methods of determining going value, one, the development cost method used by the Wisconsin Railway Commission, which involves the ascertainment of earnings, expenses, and rate of return, and carrying forward from year to year, plant cost, depreciation and deficits in earnings, as set forth in exhibit A. 19. The second method involves the determination of the reproduction cost of the item, by comparing the earnings enjoyed by the existing plant with the earnings of an assumed similar plant during the period of years assumed to be necessary for this comparative plant to acquire the volume of business of the existing plant. In ad-
394 dition to these methods we have the judgment of managers of public utilities that the value of the item may lie between one years' gross revenue and something in excess of that amount. The decisions of courts and commissions do not outline the specific method used in arriving at that value. Reference has been made in a number of such opinions to the fact that the methods mentioned have been used. The Wisconsin Commission has referred to it and it is my opinion that it was fully discussed by the Wisconsin Court in the recent Appelton Case.

Assuming continuity of operations, I do not believe that there ever is a time in the operations of the plant when additions to going value cease.

It has been suggested by certain individuals that going value may be disposed of by capitalizing the cost of establishing the business or by absorbing what the establishment of the business has amounted to in revenues but I do not understand it to be the law. To pursue the latter method to a logical conclusion, assuming that there have been no deficits and that that method of computation shall be used, is to arrive at the result that the plant with an established business is no more valuable than a plant without an established business. Which seems to me cannot be the case. The cost of establishing the business is one of the criteria of going value or development expense. The cost of reproducing that business is another. Personally I believe that the cost of reproducing the business is the safer criterion of value in the older plant. In a recently constructed plants the original cost of developing the business is the best evidence we can have. I have no knowledge of the cost to the D. U. W. Co. of establishing its business. It cannot be determined except on assumptions.

The cost of educating the public to the advantage of water under pressure is not the sole element of expense involved in the development expense or going concern. The development expense is made

up very largely of the burden of interest charges, the carrying of the plant to a point where the earnings of the plant will carry it. Of those facts we have knowledge in the present case. We know the revenue derived and we know the approximate amount of those charges. We have no knowledge of the revenue before 1895. The two plants of which this plant was formed had been in operation prior to that time. Information as to these earlier operations cannot be obtained. To the extent of the then existing revenues the business then taken over was an established business, but it has grown very markedly since that time.

It is true that I did not start with the year 1895 to determine development expense according to the Wisconsin Railway
395 Commission method. It is not true that the going value which I placed upon this plant was founded essentially upon the results thus obtained. They were of consideration but there were other considerations which were of greater import in the fixing of my judgment. It is not true as you infer that extensions made from time to time in the pipe system and supply works come into use immediately in the sense that the use is complete, or that the return is commensurate with the cost. They come into partial use. ("Discussion of the rate of growth of Denver from 1870 to 1894 as set out in the chronological statement, page 8, Exhibit C.")

Exhibit A. 20, shows the total revenues of the company from 1895 to 1913 and the expenditures for operation, taxes, and repairs, excluding depreciation or disposition of net revenue. The total revenues for 1895 are $628,333, operating expenses exclusive of depreciation $160,267. For 1910, Revenue was $799,771, operating expenses, $227,581. 1905, Revenue was $1,009,763, operating expenses $285,252. The gross revenue from 1895 to 1905 increased nearly $400,000 and operating expenses about $125,000 From 1905 to 1913 the revenue increased about $375,000 and the operating expense $185,000.

The increase in gross revenue from 1895 to 1905 was 60 per cent. The increase in operating expenses from 1895 to 1905 was 78 per cent. The increase in gross revenues from 1905 to 1913 was 37 per cent, and the increase in operating expense from 1905 to 1913 was 65 per cent. The ratio of increase in operating expenses in the last period was less than in the first period.

In 1895 the office expenses were $44,439. In 1905 $57,127. In 1913, $80,808. The office expenses go up and down. In 1912 they were $67,000. In 1895 the legal expenses were $18,591. In 1913, $45,717. The increase in office expenses for 1913 I think was occasioned largely by the investigation work of the last year in connection with the inventorying and valuating of the property, which I believe was a very necessary operating expense. We could not have refused to give the Public Utilities engineers the information for which they asked. I consider attorney's fees proper expenses to be charged against operation.

I assume that the company believed that it was in the right in the litigation in question. In this litigation to set aside the decision of the city council as to water rates, I consider the attorney's fees ex-

pended by the company a proper item of operating expense. I consider the amount of the attorney's fee here recorded very reasonable considering the work which was required. The larger sums
396 charged to legal expense involve litigation incidental to the rating and franchise cases. The last pumping works were installed, I believe, 5 or 6 years ago. The increase in pumpage expense, shown by Exhibit A. 20, from 1903 on, was due primarily to the scattering out of the city in different directions and to the building of homes on the hilltops. It was just at that period that Capitol Hill reservoir No. 2 was built and extensions made of the Capitol Hill pumping plant and the Ashland avenue stations, indicating increased consumption of water in the high districts.

The Ashland Avenue Pump station was completed in 1907. The construction of the station was charged to construction but the pumping of the water is charged to operation. That is what you were talking about in that table.

I think the increase in the cost of operation in the pump stations is a logical and natural increase. I cannot tell you in detail about the variation in the ranch expenses, except that it is my recollection that a greater area of land was under cultivation at the end of the period than at the beginning.

The decrease in Ranch expense from 1911 to 1913, was due to the fact that one of the large ranches which the company had owned and operated up to that time was sold, the Harriman Ranch. The same explanation I believe applies to the ranch revenue. The increasing cost of service repairs is due to the fact that the plant has reached an age where the consumers service pipes, in many cases, have about reached the end of their useful life and are being replaced because they are becoming clogged with rust on the inside and the consumer cannot get sufficient water through them. I have not heard anything about a burst*ed* main last Saturday or Sunday. I do not believe that the distribution pipe system is likely to be seriously damaged by electrolysis. (Reading into the record by Sen. Patterson of extracts from work on electrolysis by Samuel S. Wyer.)

There are two reasons why I do not believe that the pipes in this system are affected by electrolysis. First, we have very little evidence in this country to show that under average conditions the wasting of pipes due to electrolysis is a large factor. Second in this system some 8 or 10 years ago the pipes were bonded with the rails of the tramway company, the bonds being carried back to the power station. Before that time there had been trouble at a few points, a few times in proximity to the power station. More particularly with the service pipes where the stray current left those service pipes. In some cities street railway plants are required to provide independent insulated return circuits to carry the current back to the power house.

397 It is practically impossible to determine with accuracy the extent of injury from electrolysis in any system, all that we have to guide us is past experience in those cases where the condition has become so aggravated as to require replacement. I do not know

how many bond connections there are between this pipe system and the rails.

I do not know much about the history of the property listed in Exhibit C. as abandoned property. I do not know anything about the initial installation of Lake Archer and the West Denver plant nor how the water was supplied. In a general way I am familiar with the steam power at the West Denver plant. There is sufficient steam capacity there to distribute the water that is distributed by that station, assuming that you wish no reserve capacity. I saw the station running a few days ago when all the machines, including the water power pumps were running during the hours of peak load. (Discussion of the capacity of the West Denver station and cost of installation of new steam pump to take the place of water power pumps, supplied from Lake Archer.) Objection to interrogation concerning cost of replacement by steam unit, sustained. It is my recollection that we had original costs in the case of a few of the lands connected with the system. I think as to some of the lands in the Marston Lake region and it is my impression that we did on some of the ranches. I don't know what relation the present valuation of the lands bears to the original cost. In the light of court decisions, as I understand them, it was not necessary that we should make that investigation. It might be true that if the water company owns a very large amount of real estate that some consideration should be given to the appreciation of lands in arriving at a rating base. I remember of no case in which consideration or weight was given to that except in the Spring Valley water cases where substantially one half of the water company's property was made up of lands which is a very abnormal condition.

In this case the lands amount to a very small percentage of the value of the whole property. In water works generally in the East, land values range from 3 to 8 per cent of the entire property except in systems where there is a large reservoir system and large drainage areas, but in general less than 10 per cent. Here the figures are not very different. On the Pacific Coast in the case which I cited, nearly one-half of the property lay in lands, that grows out of course of the water right conditions. The appreciation in value of the lands may be of consideration in those extreme cases.

I think that recognition should be given to the higher use made of land in considering their value. By higher use in connection with water works I do not imply a monopoly condition. But in
398 the sense that an agricultural use is higher than a grazing use of the same land, I mean that that value may be taken into consideration. Special value, or availability and adaptability, should not be created for land when such value did not exist before investigations were made that called attention to the availability and adaptability of those lands for a particular purpose. In cases where the property is especially available and adapted only to the community or public utility acquiring it, it is against sound public policy and a just consideration of the right of the public to have public works created at a fair cost. That is limited to the situation where the property is available only for the one public use and pre-

sents quite a different situation than is presented by the property in question here.

The item of $84,747 in connection with Lake Cheesman, entitled, "Dam, preliminary and flood expenses" is made up partly of an allowance for the hazards involved in connection with such work and partly of the cost of work done on the original dam, which was incorporated in the present structure after part of the dam was washed out by the flood.

It is my recollection that the expenditure on that first dam, exclusive of the cost of litigation following the flood, was about $124,000. Then follows for the present dam, masonry $485,320 then the item, cement, $303,780. That does not represent the whole cost of the dam, there is the excavation, tunnels, and other items, also engineering and contingencies and interest during construction. The life of the dam cannot be estimated. I think it will far exceed what I have put down in the depreciation tables at page 65, exhibit A, 10. The item of stand pipes is stated on page 93. Item 5, two stand pipes at Cottage hill, the estimated useful life is 28 years. In the water works life tables published by me, (see reference p. 2026 record) the useful life is given at from 25 to 40 years. In this plant I have estimated the life of the stone and brick buildings at West Denver at 50 years, frame buildings 33 years. At Capitol Hill I estimated brick buildings 33 years, wood buildings, 22 years. In the life tables I have estimated masonry buildings 40 to 50 years, wooden buildings, 20 to 50 years. Cast Iron pipe I have given 16 inch and larger pipes 94 years, 10 to 15 inches 72 years, 6 to 8 inch 56 years, 3 to 4 inch, 41 years. In the life table published by me I have estimated pipe of large diameter at 50 to 75 years, small diameter 20 to 40 years. The difference between the local estimate and the life table is not very large. The life of wood pipe in this system is estimated to range between 41 and 47 years. In the life table published by me it is estimated from 20 to 30 years, but the fact is that some of the pipe in this system is nearly as old as the limit assumed in the life table and the pipe is still in sound condition. We estimated the
399 life of the hydrants here at 41 years. The life tables published by me give it at 40 to 50 years. The estimated life of the pumps here is 41 years, boilers 23 years. In the life tables published by me pumping and auxiliary machinery is given at from 20 to 30 years, the average age of the pumps here is already 27 years. We do not rate pumps upon any such arbitrary basis but upon their condition and ability to do service. You imply that regardless of the condition or character of the machine a man must adopt a list of estimated ages which was made years ago with perhaps a certain set of conditions in mind, and that simply because that list has been so printed, therefore, regardless of the condition of the property, a man should always stick to the list.

At West Denver station page 88, Exhibit C, I gave the life of one set of boilers, 23 years, another set 20. At Capitol Hill 24 years, at University Park station 15 years, Montclair Booster station 21 years, Ashland Avenue station 21 years. The life tables give the average life of boilers at 12 to 16 years, many of these boilers are already

older than that, still doing good service and still approved by the boiler insurance companies. I might say that those tables were made at a time when I was considerably younger and had had less experience than today. As I have stated, many of the structures in this plant are actually older than the useful life which I have given in the tables and yet are in excellent condition and destined to be in service for many years yet to come. I conceive it to be the duty of the engineer to pass judgment in the light of conditions as he finds them, not in the light of any arbitrary tables, least of all to be bound by anything which he has written before, simply on the account of a desire to be consistent with what he has written. In a general way those tables represented what I then believed to be the general limit within which the life histories of such structures generally lay under the conditions with which I was familiar. The article was written a number of years ago, and you will find in it the statement, that while these may be general limits there are many instances on record within and without those limits. The work on the Sullivan Reservoir was done before the time of the D. U. W. Co. Up to this time it has not been in use.

The structures upon which valuation is placed there are the reservoir structures themselves and have nothing to do with the diverting works in the bed of Cherry Creek. The valuation amounting to $160,164, depends upon a future use of the reservoir by the company. What a subsequent management may do with the reservoir no one knows. I do know what the intention of the present management has been and is. I have estimated for a depreciation allowance for the year 1913, $138,000, and for the year 1914,
400 $144,000 and a contingent reserve fund of $30,000 per year in addition to that. This plant will be forced to serve the city, whether it likes to or not, at least until a new plant is partly constructed. I estimate that the construction will require from 5 to 6 years if they commence now. The depreciation allowance set aside during that period may be used by the company in any way, subject to the requirement that it be accounted for to the public as depreciation upon the property. The consumers will have received a return in service in that interval of time for the rates paid. The plant is depreciating each year, depreciating in the service of the city. When the new plant is completed the people will have wrecked the company's plant, but while the wrecking process is going on the plant is actually wasting each year to the extent of the estimate, and the city has had the equivalent value in service and has used the service during the time that the plant has depreciated in that amount. Why should it not be replaced to the company?

Cross-examination by Mr. Nye:

All useless property was eliminated from the gross total of the property which I valued. The pumping plant at Platte Canon was included in the valuation. In my judgment it is useful, it enables the company to make use of the conduits ordinarily used to carry raw water, as filtered water conduits in case of emergency. I do not

know whether it has been used for any extended period. It is my understanding that the raw water conduits are so connected as to make this use possible. I did not make an examination of the records to ascertain to what extent those pumps had been so used. It is my understanding that these pumps may take their supply from the slow sand filter beds or from the underground source through a pipe that runs beneath the pump station. They are emergency pumps entirely. Most of the water delivered to Denver is measured at Wynetka. The Cherry Creek supply is measured at the Capitol Hill station and the Mississippi Street supply at West Denver.

In determining the quantity of water delivered to the city, I have made no allowance for loss in transit after leaving the point of measurement. By consumption, we mean the quantity of water which is supplied. A portion of that is always lost in the mains and services and goes into the per capita rating of the plant. In other words the reading of the meters on the consumers services never accounts for the total quantity of water supplied. If all of the water supplied was measured both at the point of supply and the point of use the measurement at the point of supply would be taken to represent the consumption, though both measurements
401 might be stated to indicate the amount of water unaccounted for and waste, but ordinarily the records of consumption include all such losses. The Public Utilities Com-ission engineers had been at work from one to two months when we commenced our valuation. The element of value developed by the use or utility of any structure was no part of the valuation assigned by us to the physical structure. The valuation placed upon them was our judgment of the reproduction cost, in other words as to Cheesman dam, for example, so much masonry could be constructed there at such a price, or anywhere else where the conditions were similar for the same price.

A substantial part of the value of the lands at lake Cheesman unquestionably grows out of the fact of the utility of the lands for reservoir purposes, but no additional allowance was made because of their use in connection with a domestic water supply. They were considered to be equally valuable for irrigation purposes.

Similar consideration was given to the lands at Marston Lake. It is my impression there that the added consideration, because of utility, was less than 25 per cent of the total value placed on the lands. In determining the value of water rights the valuation was strictly on an irrigation basis, although I have stated that in my judgment the use of water for domestic purposes was a higher use and should command a higher return, nevertheless the valuation was on an irrigation basis. From the viewpoint of reproduction cost it certainly is proper to refer to going concern value as the cost of reproducing the business. I think it is unquestionably true that in considering the question of going concern value we should take into consideration the contractual relations existing between the company and the city from 1894 to 1910 and the effect of their limitation upon the earning power of the company during that period. That consideration would apply to the computations dealing with

the cost to the owner of developing the business and would indicate that the computation made on the basis of earnings under the comparative plant method, should have greater weight.

I am inclined to think that weight should be given the consideration that under the terms of the contract in existence from 1894 to 1910, that the return permitted to the company during those years under the terms of the contract was a fair return by virtue of that contract.

Redirect examination by Mr. Dorsey:

I am advised that all of the pipe laid by the Citizens Water Company was not class A. pipe, some of it that has been taken out
402 of the ground has been weighed and found to be Class B pipe.

It is perhaps fair to say that 75 miles of the original 97 miles laid by the Citizens Water company is still in the ground. If that is all class A pipe I estimate that for the size of the system the difference in weight between class A and Class B would approximate 5 tons to the mile. Which for the 75 miles would make 375 tons, or a difference in price at the rate we allowed for pipe, of about $13,000. I think however that the allowance that we have made by making no additions for overweight pipe more than covers any such possible shortage in weight.

The total valuation placed upon the Lake Cheesman property was $3,400,000. It is my judgment that the property possesses that value for irrigation purposes. It is quite as much to the advantage of the public as to the advantage of the company that the contingent reserve allowance of $30,000 a year in addition to depreciation be made and such allowance should come out of gross revenue. In making our estimate of reproduction cost we assumed the use of trenching machines wherever they could be used, that is in the outlying portion of the city where the character of the soil and condition of congestion of the streets warranted. They could not be used in my judgment in the heart of the city or in the commercial district, or in the closely built up districts. I understood when I stated that the D. U. W. Co. was paying the city no compensation for the use of the streets it was not paying any stated sum of money to the city for such compensation. But of course, the company is supplying free water service in certain directions and is actually paying to the city the same compensation for the use of the streets that it has always paid since the beginning of the franchise. Also, if it were paying any stated sum, that payment would be a proper operating charge in which event operating expenses would be increased by that amount. The word, safe, in connection with the yield from water sources is used in the sense of being able to count upon the stated supply from the given source in the few years of maximum dryness that may be encountered in a century. We did not make close computations with respect to that matter because the supply was clearly prudently in advance of the need of the city, so we did not go into great detail in that matter. The total estimated safe yield from the various water sources, was 120.73 million gallons daily or about 187 second feet the year round.

By the comparative method of determining going value, I mean, broadly speaking, the cost of reproducing today the present income or business of the plant. That is in no way burdening the public with a value based upon excessive rates. In applying the comparative method I took into consideration and gave weight to the
403 fact that this plant operated in an arid region and for this reason reduced the going value below the value which I should otherwise have found. The existence or non existence of a franchise has nothing whatever to do with going value. I have included nothing for so called good will.

It is my judgment that the allowances made for engineering and contingencies in the reproduction cost of this plant are for such costs and expenses as would be incurred in the construction of such works. They were based upon experience which I have had and knowledge of what such amounts have been in other construction work. Interest during construction is also a proper charge. The allowance for engineering and contingencies by the former board of appraisal on the structures of this plant was 15 per cent. Objection overruled. Exception. Their allowance for interest during construction was about the same as ours about 8 per cent on the reproduction cost. I do not believe that the Wisconsin Railway Commission would admit that it had a settled practice of allowing 12 per cent for engineering, contingencies, superintendence, and interest during construction. It is my recollection that in some of the larger works, particularly the Milwaukee plant, a somewhat larger allowance was made. In passing upon that percentage one must take into consideration collaterally the unit prices to which it is applied and the character of the plant under consideration. The size and nature of the works, etc.

My estimate of reproduction cost is not the actual original cost, less depreciation but the present day cost of reproduction, less accrued depreciation in the actual plant.

It would make no difference in my judgment in the present value of the plant whether the going value or any part of it was created prior to the organization of the D. U. W. Co. Whether you call legal expenses operating expenses or something else it certainly is an expense that must be taken care of in the rates. The service pipes that were discussed by Senator Patterson in connection with the item, "Service repairs" in Exhibit A20 are the pipes owned by the consumers and do not relate to the distribution main, and the statement that they were approaching the end of their life did not apply to the distribution mains.

I told Senator Patterson that I would endeavor to supply him with a complete list of those service pipe repairs but I find that that can not be done, primarily because the pipes belong to the consumers, and the actual repair work is usually done by him. The company's charge to this account develops from the fact that whenever a leak is reported it sends its force to the ground to ascertain the cause. To do so an excavation must be made to determine whether the leak is in the service pipe,, the corporation cock, or the
404 main. If it is in the service pipe or the corporation cock and the expense of the repair is nominal the work is done by

the water company without any charge to the owner. If the expense is considerable involving the replacement of the service, the water company notifies the owner and may do the work for him at his expense or he may have it done by a plumber if he prefers, but the expense that the company has been put to to ascertain the cause of the trouble is borne by it. I am informed that a considerable amount of the increased expense on this account in the past few years has been in localities where storm and sanitary sewers have been constructed, the work upon those trenches having resulted in settlements that have caused a pulling out of the service pipe, causing it to leak. If the employes of the company find when the excavation is made that the leak is in the main itself the repairs are made and the cost is charged to the account, "Street repairs." Also shown in exhibit A20 under which all charges for the repairs to the distribution pipe system are entered.

I have with me the data that was requested by Senator Patterson as to the amount of the expenditures on the first Cheesman Dam, as shown by the books of the company. The expenditure for that work was $168,884.54. Some of the work included in this item went into the finished structure and was not estimated separately there. It is included in our allowance of $84,000 under the item, "preliminary and flood Expenses." So there is no duplication.

The depreciation allowance of $138,000 per annum is to take care only of the ordinary depreciation, and not calculated to take care of the loss in value that the plant would be subjected to if the city constructed a new plant. To make that loss good it would be necessary to practically double the rate in the interval between the beginning and completion of construction of the new plant. In valuing lake Cheesman we considered the special adaptability and availability of the lands as a reservoir site but added nothing because of the fact that the reservoir was devoted to a city supply. Nothing was added to any value in the plant because of that particular use. The allowance made by us for going value was just what it would be after giving due consideration to the question of limitation by contractual conditions during the franchise period that was raised by Mr. Nye. I think the Wisconsin Railway Commission since the Appleton case has allowed for pavement over mains in rating cases.

Recross-examination by Mr. Nye:

Some of the lands excluded from the valuation of the Spring Valley case were properly excluded, others were not, in my
405 judgment. Though I have accepted the dictum of the Court.

It is my view in rating cases that it is better to be liberal in the inclusions than to cut too closely what is necessary in the operation of the work, because ultimately if you are not reasonably liberal in the interpretation of what constitutes use you will have to allow a higher rate of return or have much more property to take care of in the depreciation account. I would not include

property not likely to be used in the near future in the rating base. The fact that the property is growing older has nothing to do with my estimate of the needs of a contingent reserv fund proportionately larger in the future than has been required in the past. My reason for allowing less going value in this case than I would allow in the East, is the fact that in the East we have more available alternate sources, which could be used by the individual, therefore the development of business would not be as rapid. It is true that the average age of the service pipes attached to the mains is less than the age of the mains themselves.

Redirect examination by Mr. Dorsey:

There is considerable difference between the life of the cast iron mains and service pipes. Service pipes may be assumed to have a life of from 16 to 30 years, while the shortest life assumed for mains in this system is 41 running from that up to 94 in the case of larger mains and I have no doubt that the actual life will be much longer than that. The fact that the plant is larger and constantly growing larger and spreading over more territory affects the requirement for the contingent reserve. I don't believe that we have included in this property any lands that would fall in the same category with those that were excluded in the rating base in the Spring Valley case. There may be a few lots, or something of that sort, not necessary, but the amount involved in their value would be infinitesimal as expressed in percentage as a reasonable rate of return from this plant, it might amount to $10,000.

Eliminating that small amount which would be negligible, there is no property included here which is not necessary.

Witness LEONARD METCALF recalled.

Direct examination by Mr. Dorsey:

I caused to be prepared a table at page 50, Exhibit C headed, "Reservoirs of the D. U. W. Co." the information as to drainage area, elevations, operating level, capacities and depth, were obtained from the records of the company. Data as to storage
406 per square mile of drainage area was obtained from computations. Offered and admitted. The table at page 51, Exhibit C dealing with the filter plants of the company was similarly prepared. Information was obtained from the records of the records of the company. The table shows among other things, the average output of the filters daily for the year 1913, and states "All of these filters have been and may still be operated at considerable higher rates with good efficiency" that is my note from an investigation of the filtration results obtained. Offered and admitted.

Mechanical filters are commercially rated on a basis of 125 million gallons per day per acre of filtering surface, which I have assumed here. For the slow sand filters I have assumed 2.8 million gallons per acre per day. Another table appearing on page 51, under the heading "Infiltration galleries" was similarly prepared from the

plans and records of the company. The column headed "lineal feet" refers to the length of the collecting gallery from end to end without respect to its height or cross section. Offered and admitted. The last table on page 51, of Exhibit C, headed "Water supplied from different sources by the D. U. W. Co. for the year 1913" was similarly prepared from information obtained from records of the company. The last column shows the percentage of the total supply drawn from each source. Offered and admitted. I cannot say whether less water was drawn from the Mississippi Street and Cherry Creek galleries in 1913 than formerly. That information may be furnished by the table at page 36, as to Cherry Creek. Referring to the table at page 36, apparently the draft is about the same. The information as to Mississippi St. may be obtained from pages 34-35, which indicate that the draft for the year 1913 was considerably less than heretofore. These drafts cover the flow for the entire year, whereas Mr. Anderson's testimony applied only to the summer season flow, and the galleries flow more in summer than in winter.

Cross-examination by Mr. Nye:

On pages 41-42-43 are computations showing the capacities of the clear water conduits based upon the assumption of maintaining certain levels in the distributing reservoirs. If the levels are reduced the carrying capacities of the conduits may be materially increased, except the Cherry Creek Conduit which delivers over a weir at the Capitol Hill Reservoir. During periods of heavy drafts the conduits discharge directly into the mains without carrying the water to the reservoirs at all, reducing the friction loss and increasing the rate of discharge. Much of the water which is con-
407 sumed, never reaches the reservoirs at all and the increase in draft before the water reaches the reservoirs from whatever source it originates results in an increased delivery from the clear water conduits. There is no table which shows the maximum delivery possible from those conduits. We can make such a table or your own engineers can prepare it.

In computing those conduits capacities I assumed a free discharge from the conduit into the reservoir at the water level indicated. It would make no difference whether the conduit itself discharged into the bottom of the reservoir or near the top at the level determined upon. The Cherry Creek conduit discharges at the top. The same is true at Mississippi Street. The other Capitol Hill lines and the Ashland Avenue lines, as I remember them, discharge into the bottom of the reservoir. The list of abandoned property which I have given you and which has been marked Defendant's Exhibit 14, corresponds to the list given at pages 98 to 100 Exhibit C except that in the document marked Exhibit 14, values have been extended for the several items. No part of this property was included in my total valuation of $16,038,000.

Redirect examination by Mr. Dorsey:

In the table of capacities of clear water conduits, I have assumed that all of the water indicated by those capacities would be delivered into the reservoirs at the end of the conduit line. In actual operation water is taken from the conduits before they reach the reservoir, reducing friction loss, so the capacity of the conduit is greater than that here shown. Take for example conduit No. 3 on which my estimated capacity at the reservoir ranged from 8 million to 9.7 million gallons and which the records of the company show has actually delivered 23 million gallons daily. That added delivery is accounted for by the fact that the water was taken from the conduit on the way to the reservoir, in other words a shorter distance must have been traversed by the water and the water must have been delivered at a lower level than here assumed. The capacity of the system to deliver water during periods of maximum draft is greater than the capacity of the conduits, because under those conditions water will be drawn from the reservoirs which will be replenished when the heavy draft ceases. That condition exists in Denver every day in summer. Except perhaps on rainy days when there is no draft for sprinkling purposes.

408 Recross-examination by Mr. Nye:

If any of these clear water conduits delivered three times the capacity here rated it would be under such conditions as reduced the pressure to a point where the buildings in the higher part of the zone of supply would be without water.

Redirect examination by Mr. Dorsey:

I do not remember the height in this system at which water is delivered where the pressure is furnished solely by the gravity system. The people who take water from the gravity service, take it at a point in all cases which is substantially below the level of the water in the reservoir which I have assumed in my tables.

Recross-examination by Mr. Nye:

The location of the consumer affects the discharge of the clear water conduit in respect to the draft which the consumer makes as affecting the friction and the variation of the hydraulic grade. Exhibit C. in its entirety offered and admitted, except as to one page, 49, bearing upon the testimony of Witness Goldsmith.

Witness GEORGE GRAY ANDERSON.

Direct examination by Mr. Dorsey:

I reside in Denver. Am a civil engineer. Was educated in Aberdeen, Scotland. In Robert Gordon's College, and in the University of Aberdeen. Then was apprenticed 5 years to a firm of engineers mostly engaged in water works, sewage and land drainage, includ-

ing the term of apprenticeship have been engaged in the practice of engineering 40 years. Was employed by the London & Northwestern Railway Company in London, England. In the spring of 1880, came to Colorado as assistant engineer of the Northern Colorado Irrigation Company's canal, remained with that company as assistant engineer, chief engineer, and general superintendent until 1890. The company was known locally as the English company and had large works here with which I was connected. Have since been actively connected with irrigation and water supply projects. The largest of which were in Alberta, Canada, covering about 250,000 acres of land. Built the water system for Greeley, Colo. a number of reservoirs and irrigation works on the Arkansas River and in the San Louis Valley. The last three years have been mostly in California in connection with the works of the Spring Valley Water Company and the Pacific Gas and Electric company of San Francisco. I am familiar with the water rights in the state of
409 Colorado, particularly on the South Platte River and its tributaries, as to their yield capacity and value.

I first became familiar with the property of the D. U. W. Co. about 18 years ago, since which time I have frequently been consulted by officers of the company concerning water supplies, water rights, and matters of construction. I first investigated the water rights of the company as a whole about 1907 for the purpose of preparing data and reports for the board of appraisal engaged in valuing the property which reported its findings, March 20, 1909. The investigation covered the entire water rights field with respect to the availability, reliability and the then value of the water rights of the company. The flow of the streams, and amount of water that might reasonably be relied upon from the water shed from which the rights are supplied.

Have recently made further investigations of the water rights in connection with the recent appraisal by Mr. Metcalf and myself. Am familiar with this book which is Exhibit C. I cooperated with Mr. Metcalf in the valuation of the entire property of the company and the conclusions set forth in exhibit C. represent our joint conclusions as to that value. It is also true as to the several items of reproduction cost, depreciation, and the detail of the inventories, set forth in exhibit C. I was present in court and heard and concur in the testimony given by Mr. Metcalf in respect to the investigations conducted by us and the conclusions which were reached.

I made a special study of the water rights which are referred to beginning at page 117 exhibit C. and in greater detail at pages 417-27 also pages 15-19. The effect of my investigation of the water rights at this time was to bring my previous investigation down to date. I examined particularly the statements of claim upon the water rights, the water supply from the streams and the yield available for the rights and considered their value and the changes that may have occurred in their value since my previous investigation. I then combined the various rights in groups according to the manner in which the supplies are grouped in the operation of the works. In determining the value of the rights I based my conclusions upon

their value solely for irrigation purposes as though they were separated and taken away from supplying the city of Denver with water for domestic purposes.

In effect the value assigned to the rights is the junk or wreckage value that would remain if they ceased to be used for the purposes for which they are now used. The rights possess a greater value for domestic supply purposes than for the purpose for which I have valued them. They also possess an added value for irrigation
410 purposes assembled together as they are in such a large body of rights capable of yielding a large supply. But I have considered neither that element of value nor the element of value for city supply purposes. I have simply valued them grouped together as they are today and as I find them. It would be necessary for any one coming here today to duplicate this water system, to reproduce the physical structures and the land and also to reproduce by purchase or otherwise the water rights necessary to furnish the water supply. In my opinion it would be impossible to reproduce water rights equivalent to these or adequate for the supply of the City of Denver by original appropriation. It would be necessary for anyone attempting to reproduce these works to obtain his water rights by purchase or condemnation. I never have seen so much water in the Platte River for so long a period as this year in the 34 years during which I have been familiar with it. It is more necessary for a water supply for municipal purposes to be continuous and reliable than where the supply is used for irrigation purposes. For this reason it would be impossible to obtain a supply for city purposes dependent upon flood water flowing in such an unusual year. In my judgment it would be impossible to acquire by purchase or condemnation a water supply equally as adequate and available as the supply of the D. U. W. Co. for the use of the City of Denver at the price which I have assigned to these water rights as their present irrigation value. It would cost more to obtain a reliable and adequate supply.

The supply of the Platte River is over appropriated. The appropriations having been effected by the construction of canals, reservoirs, etc., large in extent and expensive in character for the utilization of the water. If a water supply, to reproduce this water supply, was obtained by purchase or condemnation it would take it from those who are using the water through these structures with the result, if the structures could not be used in the new enterprise their value would be destroyed. A large acreage of land is irrigated by the waters of the Platte River and its tributaries through the structures mentioned and so much of this land as the water is taken from, to reproduce this supply, will at once go back to its original condition as dry land much depreciated in value. The amount of that damage I would not attempt to estimate, but it would be great. Those elements of damage to lands and structures would enter into the price that would have to be paid for the water rights by one purchasing to assemble them by purchase or condemnation. I have not taken that element into consideration in fixing the value of these lands, but have simply

put upon these rights the values which I consider are current for waters of that kind devoted to irrigation purposes. The High
411 Line Canal structures are to the south and east of Denver. I am personally familiar with the lands than can be irrigated under that system. In 1882 I personally made a complete survey of the land lying under that system from the canal northerly almost to the Cache La Poudre River and to the east to a point near Platteville. I am familiar with ditches and reservoirs through which the waters of the D. U. W. Co. might be applied to lands for irrigation purposes, and with lands to which they may be applied. There is a demand for such a water supply, sufficient to absorb the water produced by the rights of the D. U. W. Co. In valuing these water rights I have, as I stated above, divided them into groups, as I found them in the physical application to the system.

Group No. 1 listed at page 117, Exhibit C is composed of items 1-4, 13-17 and 21, to which I assigned a value of $1,150,000. These are the rights taking the supply from the Platte River at Platte Canon and from Bear Creek, combined and operating through Marston Lake. (Detail of method pursued in arriving at the valuation of the rights contained in Group No. 1.) I assumed from the rights in Group No. 1 delivered through Marston Lake an average annual supply of 38,468 acre feet which I have valued at $60 per acre foot. Making a total of $2,308,080, from which should be deducted to determine the net value of the water rights the value of the structures appurtenant thereto, amounting to $1,163,886 leaving a net value of the water rights $1,154,194 which I have rounded out at $1,150,000. The net average annual yield from the Platte Canon sources is 37,484.6 acre feet, deliverable through Marston Lake, from which I have deducted 3,909.6 acre feet for evaporation and seepage loss from Marston Lake estimated at 6 feet vertical annually, leaving a net available supply of 33,575 acre feet. The yield through the Harriman Ditch from Bear Creek I have estimated at 6,840 acre feet annual average, making a total of 40,415 acre feet from which I have deducted 1,947 acre feet from the Bear Creek supply, that according to the records would be available in the months of April and May when Marston Lake was full and before drafts commenced from the stored supply in the reservoir leaving the net amount of 38,468 acre feet upon which I have computed the value. This 1,947 acre feet however could be made available through exchange but I have not considered it in fixing the value. This estimate of yield is on the basis of 100 per cent effective delivery of the water ascertained from the records of the stream with relation to the priorities of the ditches.

It is a guaranteed supply without any question. Every element of doubt or uncertainty of the water product having been
412 eliminated from this consideration. It is not on the basis of the purchaser sharing pro rata in whatever the water rights may be capable of yielding as is the ordinary practice in handling irrigation water. The storage capacity of Marston Lake is 19,794.7 acre feet. In utilizing this quantity of water the winter flow from October to April would practically fill the reservoir. The flow for

the months of May and April would not be put into the reservoir. The flow of the South Platte would be handled either by storage in Lake Cheesman or exchanged with other ditches. That of Bear Creek might be exchanged to some extent but for the purpose of my computation I have eliminated the amount available from that stream for those two months. After the beginning of June and the beginning of the demand, the withdrawal of water from Marston Lake would be in such volume that the storage could be withdrawn and the normal flow from the Platte River and from Bear Creek would be taken through the lake and treated as stored water.

Group No. 2 shown at page 117, Exhibit C consists of items nos. 5 & 6 valued at $200,000. It is the supply from the Mississippi St. Galleries under two appropriations from which on the basis of the records from 1900 to 1913 I estimate the yield at 4,459.6 acre feet for the irrigating season and 2,092.1 acre feet for the non-irrigating season making a total of 6,551.7 acre feet for the total yield for the year. This water is practically stored water taken from the gravel beds beside the stream, a source that is constant and dependable at the season of the year when such water is required. The irrigation season flow can be taken from the conduit directly back to the river and diverted below Denver wherever desired. The non-irrigating season flow would require a storage down stream to be utilized to its full value. Having that in mind and to be conservative I have treated both the irrigating season flow and the non-irrigating season flow as requiring storage, and estimate a cost of $20 per acre foot to cover such storage, leaving a net value per acre foot for the 6,551.7 acre feet of $40 or a total value for the water of $262,068 from which is deducted the value of the plant appurtenant to the diversion of the water amounting to $72,980 leaving a net value of $189,088 which I have rounded out at $200,000.

In determining the yield from these rights I have based the quantities upon the actual quantities obtained from 1900 to 1913. That does not in my judgment represent the total amount available from this source of supply, but I have left that out of consideration in my valuation. The water diverted by these galleries is not water flowing in the surface water course of the stream. In making this de-
413 termination I did not consider the claim that the appropriation related back to Dec. 20, 1870, though the actual appropriation occurred in 1878. I followed the same plan with reference to relating back the appropriations wherever such claim is made by the water company. I think $20 an acre for storage facilities is an ample allowance. I did not make any allowance in my valuation for the power rights of the Archer Canal, the Platte and Denver Ditch, or the Rough and Ready Ditch, which in my judgment are simply protective of the quantities of water available from the rights to which values were attached.

These power rights are listed in items 20 and 21 at page 118 of Exhibit C. My purpose here has been to ascertain the value of the water rights from the viewpoint of their productiveness.

Item No. 7 Cherry Creek galleries rights, valued at $60,000. The diversion is made in the same manner as at the Mississippi street

galleries and I estimate the yield during the irrigating season as 3,424 acre feet sufficient to irrigate 2,000 acres of land to which I have applied the value of $60 per acre, a total of $120,000 from that I have deducted the value of the structures appurtenant to the diversion of the water amounting to $49,252 and I estimate that ditch construction to the amount of $10,000 would be necessary for the proper utilization of this water. This leaves a net value for the water in round numbers of $60,000. There are a number of areas of 2,000 acres to which that water can be applied.

Exhibit A 27 is a record of the stream discharge of the South Platte River at Platte Canon from April to Oct. inclusive for the years 1887-1913, with the notation as to where the records have been found. That is one of the tables to which I referred in my testimony.

Exhibit A 28 is a table showing the discharge of the South Platte River at Platte Canon for the months Nov. to March inclusive from the years 1887-1913 so far as the records show them, with notations as to where the records are obtained. Also notes as to the percentage of supply compared with its appropriation available to the Platte Canon Ditch during these months. Exhibits A27 and A28 offered and admitted. Exhibit A29 is a copy of the record of the actual delivery of water of the Mississippi Street galleries to the West Side Pumping Station of the D. U. W. Co expressed in second feet and acre feet. Information contained in Exhibit A29 taken from the records of the D. U. W. Co. It is the table to which I referred in testifying about the water available from the Mississippi Street galleries. Offered and admitted.

414 Item No. 8 in the list of water rights at page 117 Exhibit C refers to the Platte Canon filter galleries, value $64,000. The record of yield from these galleries show an average supply for the irrigation season each year of 4,178.7 acre feet and for the non-irrigating season 2,709.5 acre feet actual production.

Exhibit A30 is a table showing the quantities of water actually produced by the Platte Canon galleries for the years 1900-1913.

This water could be returned to the stream about a mile below the galleries and diverted again by ditches below or in exchange with the Highline Ditch or the winter flow occasionally diverted to Marston Lake in conjunction with the Platte Canon Ditch rights. My analysis shows that about half of the winter flow or about 1360 acre feet representing a value of about $80,000 could be so diverted. Of the summer flow 2418 acre feet available from June to Sept. could be so diverted, the value of which would be $145,080.

However, in the consideration of the value of this item I have eliminated all of the winter flow and all of the summer flow except the 2,418 acre feet available from June to Sept. inclusive. The difference between that and the total yield available of 6,888.2 acre feet being regarded as for the protection of the Platte Canon Ditch or left as available for some purpose in direct flow that might be developed. From the $145,080 is deducted the value of the structures appurtenant to the diversion of the water which would leave a net value of $63,532 rounded out as $64,000. The ignoring of this large quantity of water which is now produced and applied to a beneficial

use is illustrative of one of the reasons why these water rights are more valuable for city purposes than for irrigation. There is a continual flow and continual consumption at the present time. The intake of the High Line Ditch is about a mile above the Platte Canon works of the D. U. W. Co. There are no ditches intervening between the High Line intake and the water company intake. There are large areas under the High Line Ditch not now supplied with water or not adequately supplied that could absorb the water furnished by these rights of the D. U. W. Co. Item No. 9 on page 117 of Exhibit C is the 34 inch conduit right, separate and distinct from the Platte Canon Ditch and the Platte Canon galleries. The conduit can get a limited supply during peak flows of the stream. I have placed a value of $1000 per second foot on its appropriation of 24.75 second feet taking into consideration the fact that it is behind the High Line Ditch the rights of which are valued at $1250 per second foot. Ordinarily this conduit is used by the water company to carry the Platte Canon Ditch appropriations. The value given here is solely upon its own appropriation dating from the year 1892.

415 Item No. 10 40 inch conduit water right valued $30,000 is in all respects the same as item No. 9 except somewhat later in date. For this reason I have reduced its unit value from $1000 to $800 per second foot, which upon 38.08 second feet makes $30,465 rounded out as $30,000. The value is based upon the value of the rights in the High Line Ditch scaled down for the later appropriation which dates from May 1899.

Whenever there is water enough to supply the High Line Ditch there usually is water enough to supply items Nos. 9 and 10. Item No. 11, page 117, Exhibit C is a right for 50 acres in the High Line Ditch, market value $1250.

Item 12. Lake Cheesman, Value $2,000,000. Explanatory on this item I have prepared a number of tables showing the stream flow at Platte Canon and at Lake Cheesman from 1900-1913, the estimated available storage each year and the effect of a draft upon the reservoir of 60,000 acre feet per annum for irrigation purposes. These tables show that from 1899-1914 a total storage, less evaporation could have been accomplished of 912,251 acre feet or an average of 57,016 acre feet per year, based upon the provision of the decree for the reservoir which gives it the right to fill to its maximum capacity once a year if water is available. Exhibit A31 shows by years the storage accomplishment just mentioned. The capacity of Lake Cheesman is 79,064. acre feet. I assumed an annual draft upon the reservoir of 60,000 acre feet. In the ordinary operation of the reservoir that draft would not be called for in normal years, because the rainfall would in part take care of the needs of the lands under the reservoir. I have ignored this fact in my consideration however, and have treated as though 60,000 acre feet were drawn out each year, thus resolving the doubt, if any existed against the reservoir, by subjecting it to the severest test possible. Exhibit A32 shows the stream flow at Platte Canon, and Lake Cheesman, and the amounts in second feet and acre feet available for storage in Lake Cheesman,

the evaporation and total storage in acre feet from 1900-1913. Tables are compiled and computed from official records.

The last column in the tables show- the quantity of water in storage at the first of each month. These tables are supplemental to and supply in greater detail the information contained in exhibit A31. Exhibit A33 is a table showing the flow of the South Platte River at Platte Canon for 1899. Exhibit A31, A32 and A33 offered and admitted. There is no record of stream flow at Lake Cheesman for 1899 but comparing the stream flow at Platte Canon for that year and with other years for which there is record at Lake Chees-
416 man I am satisfied that the reservoir could have been filled to its full capacity in that year.

Ignoring the year 1899 there would be available in the 15 years 1900-1914 inclusive an average supply of 54,397 acre feet per annum or an average annual delivery of 90.66 per cent of the full supply of 60,000 acre feet. There would be excesses in the stream flow in some of the years to allow storage above the maximum capacity in those years so I have taken the result from the table including the year 1899 of 57,016 acre feet as the average safe annual delivery from the reservoir. In my judgment that is a safe assumption based upon the records and my familiarity with the streams themselves and the reservoir. The storage decree of Lake Cheesman is relatively early. There are a great many storage appropriations on the Platte River later than Lake Cheesman. Assuming a safe annual delivery of 57,016 acre feet the value of the reservoir at $60 per acre foot is $3,420,960, at that value the maximum capacity of the lake 79,064 acre feet is worth $43.27 per acre foot. From the gross value stated I have deducted for the structures and lands at Lake Cheesman a total of $1,426,727, leaving a net value of water rights of $1,994,233, rounded out to $2,000,000. $60 per acre foot is a fair and reasonable price for that water for irrigation purposes. The usual method of selling reservoir water rights is on the basis of maximum capacity, the buyer buys space in the reservoir and takes his pro rata share of the water obtained. My estimate of value is based upon the average reliable annual supply. In the period of 16 years there are some deficits below the 60,000 acre foot basis, but the 91 per cent efficiency over the whole period would be and is regarded by irrigationists as practically 100 per cent efficiency particularly as one of those years was the lowest in stream flow recorded in the country.

I know of no reservoir in Colorado, which has such a record of safe delivery particularly where application is made of the continuous draft for the full amount each year. No additional structures are necessary to make this water available for irrigation. The water can be turned down the river and diverted by ditches already constructed. In my judgment there is a ready market for all of that water.

Item No. 13 page 117. Exhibit C. Harriman Ditch company's shares of stock. Water available is included in Item No. 1. Item No. 14. Soda Lakes Reservoir and Mineral Water Company shares of stock yielding 440 acre feet at $60 per acre foot makes the water

value $26,400, represented by 110 shares of said stock having a market value of about $250 a share makes the stock value $27,500, which checks with the water value.

417 Item No. 18, 72 shares of stock in the Bergen Ditch and Reservoir Company valued at $30 an acre foot for 360 acre feet. $10,800. Excluded from the total value of water rights because it is for irrigation purposes exclusively. Item No. 19 Harriman Reservoir valued at $32,000 net also excluded from the total water right value because it is used for irrigation.

The fact that I included no value for the Archer Lake power rights in my valuation for water rights for irrigation purposes does not mean that that right possesses no value as at present used for power in connection with the water supply of the city of Denver. The rights of way, lands, and apparatus at the pumping station used to apply this power right are included and properly included in our valuation of physical property and in the rating base. I have treated the power rights of the Rough and Ready Ditch furnishing the Littleton Mill with power in the same manner as the Lake Archer rights and for like reason. Also the Platte & Denver Ditch rights. The next item on page 118, Exhibit C is a 20 acre water right in the High Line Ditch used for irrigation and valued at 500 dollars, excluded from the total water right value.

The total value for water rights that I have included in the rating base is $3,530,000. That is the total aggregate value arrived at by me through the processes described and is the value of the water rights for irrigation purposes. It includes only the water rights which are made use of for the city water supply. The price of $60 per acre foot is the fair value of the water rights exclusive of the cost of maintenance that may occur after their purchase, that is the plan upon which water rights ordinarily are bought and sold. The maintenance cost on Lake Cheesman would be much less than the usual maintenance cost on reservoirs because of the superior construction. That would make the water rights more desirable and more valuable.

The Platte Canon ranches were included in our valuation of $16,000,000. Through possession of these ranches the company is at all times able to make full use of the water available under its water rights and protect itself against the claim of abandonment by non use. We have placed a value on the reservoir lands considerably in excess of the value of surrounding acreage because in my experience the acquiring of lands for such purposes has invariably cost much more than the normal agricultural value of the land. The Lake Cheesman lands are particularly valuable as a reservoir site. That is also true of the Marston Lake lands.

Valuation allowed for lands is unimportant however because the reservoirs were valued as entities including water, land and
418 structures. So if the land value were reduced the water value would be increased to the extent of that reduction. I prepared the tables on page 13, of Exhibit C under the heading "Safe yield of water sources for irrigation purposes." In that table the yield from Lake Cheesman is stated at 71,315 acre feet per annum.

That takes into consideration the excess water which I stated in my testimony concerning Lake Cheesman was available over and above the rights to store the capacity of the reservoir. The table shows the yield from Cherry Creek as 5800 acre feet. That is the whole year's supply. I valued only the irrigation seasons supply of 3424 acre feet. Table offered and admitted. I prepared the table on page 14, of Exhibit C headed "Sources of water supply". The statistical data is obtained from the records of the D. U. W. Co. Table offered and admitted. Pages 24-29 Exhibit C contain tables of run-off and stream flow records. The figures of monthly mean discharges found in those tables are the figures I employed in my estimate.

At pages 30-36 Exhibit C are tables showing draft of water from various sources by the D. U. W. Co. They are the tables upon which are based my conclusions as to the safe yield from these various sources.

Cross-examination by Mr. Nye:

I meant by bringing my investigations down to date that I brought down to date the records of stream flow and estimates of yield of the water rights that I had used up to the date of the other appraisal. In making this valuation I started from the very beginning and worked each right out separately. I applied the second foot basis of value in the cases of the 34 and 40 inch conduits and the High Line Ditch. I applied the acre foot value to the other rights because they were reservoir rights or rights of like character that could be relied upon for 100 per cent efficiency when wanted. I considered the irrigation season to be from April 1, to November 1. That period is not fixed legally except that it is designated as the time during which ditch corporations may be called upon to furnish water. I have examined the reports of the commissioners and they show that April begins and October ends, practically the irrigation season draft. I testified and made affidavit before the board of appraisers as to the value of the property of the D. U. W. Co. in 1909 and placed a value on the water rights of the company of $4,879,000 from which was to be deducted structures. I did not value the water rights separately from the structures. The valuation placed by me on Lake Cheesman at that time was $3,500,000. The month of June is the month of maximum demand for water. Ordi-
419 narily stored water is required in the month of June. Ordinarily water is not available for storage in the month of June. There are years when there is an excess of water in that month. I used the records of the State Engineer's office pertaining to the demands upon the stream as a basis for my testimony. The assembly of water rights and the reliability of supply give an added value to the rights under consideration for irrigation purposes. I took that into consideration in fixing my price of $60 per acre foot.

The considerations go together, hand in hand, based partly upon the character of the service and partly upon the large volume of that character assembled in one mass. The larger volume and larger areas to be supplied may increase the difficulties of application of the supply but the first requisite is the difficulty of finding so large a

body of water for so large a body of land. The combination of direct flow rights of early priorities backed by large storage rights enable you to assure the consumer of his 100 per cent supply at all times. I contemplated using the water stored from the direct flow rights in the same season. The Mississippi Street rights are treated as capable of being stored because their use has been developed for the year round. There are numerous reservoirs down stream where these rights can be stored. If the city in obtaining a new water supply acquired water rights by purchase or condemnation it would pay not only for the water but for the value of the structures and lands damaged by the taking of that water. So that if any of these structures were never thereafter used they would necessarily be paid for. After this water was taken from such lands and structures and the entity compensated for they might be used in absorbing the present water supply of the D. U. W. Co. That would be a question of a development of trade, however. There are other structures in existence now without an adequate water supply through which this water could be put to a beneficial use.

There is plenty of land that can be irrigated from the High Line Canal and extensions thereof to absorb all of the water supply of the D. U. W. Co. and which is capable of standing the cost of $60 per acre and more. I think you could find plenty of ready markets for the water from the Mississippi street galleries at the price fixed and more. The city could not obtain the winter flow of water through the purchase of irrigation rights because the rights of the D. U. W. Co. now absorb the stream flow during the winter season. That right of the water company has been established for any use that it may make of it as I see it. I testified that in determining the value of these water rights I did so on the basis of water product, and
420 did not regard the claim of relation of priorities back to 1870.

There are 93½ feet of appropriations out of the Platte River prior to the last appropriation of the Platte Canon Ditch (List of said appropriations).

The first appropriation of the Platte Canon was July 30, 1861. 4.7 second feet.

Second appropriation Dec. 30, 1863, 34 second feet. Third appropriation Dec. 30, 1864, 17.3 second feet. Deducting for the short capacities of some of the prior ditches there remains 74.1 second feet ahead of the three appropriations of the Platte Canon Ditch, or a necessity of 130 second feet in the stream before the Platte Canon Ditch can obtain its full appropriation. During the non-irrigating season the records show that the Platte Canon Ditch could obtain 96.4 per cent of its appropriation of 56 second feet. In my calculations I have further reduced that figure to 88.07 per cent. This was due to my calculations of storage for Lake Cheesman.

I only valued the net product of the Platte Canon Ditch after making this deduction. As a matter of fact so far as total value is concerned it made no difference whether I stored that water in lake Cheesman or Marston Lake. However, Lake Cheesman is valued on the assumption that during the winter season all of the flow there is stored in the lake, so if I value that amount at Lake

Cheesman I must take it from the Platte Canon Ditch. If I don't store it at Lake Cheesman then it comes down to the Platte Canon Ditch and I value it there. The surface area of Lake Cheesman is 874 acres, Marston lake 651.6 acres. In determining the amount of water available from the winter flow of the Platte Canon Ditch I took the period from November 1 to March 31. And the supply 14,771.5 acre feet. The 37,484.6 acre feet from the Platte Canon ditch was a full year's supply. The figures from Bear creek 6840 acre feet was a full year's supply. I treated these rights as a group serving Marston Lake.

I made no additional allowance in value for exchange water. I pointed out that 1940 acre feet from Bear creek could be exchanged but I did not value it at all. It could be *sorted* in Marston Lake if the reservoir had a greater capacity. I do not consider merely running water through the lake as storing of that water. But in effect it is storing. You pass the water through the lake during June, July, Aug. and Sept. at the time of maximum demand. In effect it is stored water because you can draw it at any time. If the demand fluctuates it piles up in the reservoir until the day it is needed. simply using the reservoir as an equalizer.

I assumed that the right to store that water in Marston Lake in the non-irrigating season has matured by the continued
421 use for beneficial purposes of the rights of Platte Canon Ditch and from Bear Creek. That would not be true of any other water supply than the D. U. W. Co. because its rights absorb the winter flow of the South Platte river and no other ditch can get it. Not even the city and its inhabitants, because the Platte Canon Ditch right has matured and become a vested right against the river for that time. I do not understand that any of the claims of the D. U. W. Co. to an all year round use have been decreed but understand that they are now pending in court.

On the Cherry Creek galleries I allowed 3424 acre feet for the summer season. I limited it to the irrigating season because there was no immediately available storage that I knew of. I took into consideration the appropriations prior to both the Cherry Creek and Mississippi Street supplies but made my valuation solely upon the yield. I assumed that these yields were in no manner interfered with by priorities. In making the valuations I assumed always that the water rights claimed by the D. U. W. Co. were owned by them. And also assumed that the existing right was an all year round use and could now be changed and made as available and effective for a yield of water for irrigation use as they are now made effective for a domestic use. I made no separate valuation for Lake Archer Power right. I made an investigation of how much pumping was done by the power water.

I assumed a different value and a different duty for the Cherry Creek galleries water than for the other rights because of the difference of delivery. It is a continuous flow that might be too much at one portion of the season and too little at another. I took the record of stream flow at Platte Canon for 1900 and 1901 from the High Line Ditch Measurements because they are the only records obtain-

able. There are no records of the winter flow at Platte canon from 1887 to 1895, 1899 and 1900 also are missing, because there are no records. The records from 1902-1908 are from observations by the D. U. W. Co. at Platte Canon corrected for storage at Lake Cheesman. In determining the gross flow at Platte Canon I treated the records as though Lake Cheesman did not exist. I made no effort to assume anything for the years where we have no record, that would be pure imagination. I would not say that the Mississippi Street galleries are operated to their practical capacity. I have simply taken the record as shown without expressing any opinion. I think the yield from Cherry creek could be enlarged.

I think my estimate that Lake Cheesman could have been filled in 1899 is a well founded estimate. It is based on the stream flow at Platte Canon for the year next preceding the Cheesman record. The tabulations of storage for the years preceding the completion of Cheesman Dam are to some extent simply tabulations of what might have been done if the Dam had been theretofore completed. In other respects they are actually what was done in the way of storage.

422

There was not very much actual storage until 1904. There is no line of demarcation in the exhibit which will indicate where actual storage commenced and theoretical storage quit. It is not contended that the reservoir in practice has been drawn on in any one year for 60,000 acre feet. In making my valuation I did not figure on the duty of water at all. I was valuing upon the basis of the acre foot. I considered the supply particularly as a supplemental supply deliverable in the latter part of the irrigation season rather than as complete supply. The value is predicated partly upon this theory of supplemental supply and partly upon the fact that Standley Lake and Antero and similar projects obtain a ruling price of about $50 an acre foot maximum capacity of the reservoir in which the purchaser takes his chance on the yield which from my experience in the northern part of the state runs anywhere from 60 to 70 per cent. So that the real value on delivery is $75 to $80 per acre foot. There are large acreages dependent now upon inadequate direct flow rights that could be expected to buy an additional right at the rate of $60 per acre foot to give them a full and adequate supply. If the supply of the D. U. W. Co. was used for a complete supply I would put the duty at about 1½ acre feet which would make the water right cost $90 per acre of land. In my judgment the lands in the immediate vicinity of Denver which could be served by this supply could well afford to pay $100 an acre for such an adequate and abundant supply.

In reducing the draft of the priorities ahead of the Platte Canon Ditch I made the deduction because that was all the water that those ditches had diverted for a number of years. If in the future they should demand more water it is balanced anyway by the fact that I have taken no notice of accretions to the stream below the Platte Canon Ditch, which would more than equalize.

If the High Line Ditch had water 214 days in the year one second foot valued at $1250 would produce 428 acre feet making

the acre foot value practically $3. There are records of the High Line getting water only 30 days in the irrigating season. It is in no sense a dependable supply. I assumed that as in all reservoir projects the consumer bore the expense and loss in transit. The supply is guaranteed at the reservoir. The use of water in Denver
for the year 1913 was at the rate of approximately 70 cubic
423 feet per second and in 1910, 75 cubic feet per second.

Lake Cheesman is entitled to store every year if the water is available 79,064 acre feet regardless of how many times it partly fills and partly empties to accomplish it. And in years of excessive stream flow after having once filled it could store more if the right of junior reservoirs were satisfied. The estimated irrigation yield of the rights of the D. U. W. Co. upon which my valuation was based is 111,736 acre feet per annum. Approximately 122 million-gallons daily.

The safe yield for domestic purposes may average as great but you could not afford to maintain the same steady draft. 102 million gallons daily safe domestic draft is 153 second feet, or twice the daily supply furnished in 1910 which was the year of the greatest demand. In actual practice the High Line Ditch never draws its full appropriation. 1184 sec. feet. Its actual capacity is about 600 second feet. I believe it has drawn that much. If the Rough and Ready Ditch were in adverse ownership it could in winter interfere seriously with the rights of the Platte Canon Ditch. In making our final determination of values for rate making purposes we referred to original costs where we could find them. We did not take such costs into consideration in connection with the purchase of water and land, or water rights. We did to a certain extent as to the Lake Cheesman lands. We also took into consideration that in some of the later purchases of land at Marston Lake as much as $200 an acre had been paid. I think going concern value is a proper item to be added as part of the valuation for rate making purposes. I think the items of paving and service connections also are proper items. I don't think that the fact that the company has made a profit on the establishment of those corporation cocks would affect the principle. The $60 per acre foot value on the Lake Cheesman water rights includes water, land, structures, and the entire property. The $60 per acre foot is the value of the water on the market and from that is to be deducted the cost of developing it. The supply of 57,016 acre feet at $60 per acre foot produces a total value of $3,423,960 but in order to get that value you must invest $1,426,000 in the structures for its diversion and storage. The value of that water is not to be based upon a cubic foot per second rate like a direct supply spread over the whole irrigation season, because its value inheres in its ability to be delivered at the critical season of the year in large quantities.

Redirect examination by Mr. Dorsey:

The irrigating season as applied in the practice of irrigators ordinarily extends from the 1st of April to the 1st of November.
424 The non-irrigating season from November 1st, of one year, to April 1st following. I do not think there is any useful

purpose to which water could be applied for direct irrigation of crops between November 1st and April 1st. I considered the assembled value of these water rights because of the unusual volume assembled and the fact that there was immediate ample market for it and irrigation purposes. I added nothing to the unit price per acre foot on that account. I added nothing to the unit price because of my belief that it would be impossible to assemble another such body of water rights at that price.

The intake of the Platte Conan Ditch is above the intakes of all of the prior rights in District No. 8. The farthest of the prior rights below is about 12 miles. Part of the supply of these prior rights is made up from accretions to the stream below Platte Canon. Handling the water supplies of group No. 1. through Marston Lake in the manner outlined is equivalent practically to filling the reservoir twice each year. Though as a matter of fact there is but one storage filling and the direct flow rights simply use the reservoir as a channel through which they are applied to the irrigation of crops during the same season. The intakes of the water company's conduits are immediately adjacent to the Platte Canon Ditch. The water rights of that ditch used for domestic purposes are now diverted through those conduits.

The Cherry Creek galleries are under the jurisdiction of the water commissioner who is under the general supervision of the State engineer. The water rights of the D. U. W. Co. are available at the proper season for a supplemental supply. I considered this in assigning the value. The safe yield of water rights for domestic purposes is much less in quantity than the safe yield for irrigation purposes. Because in furnishing a domestic supply it is not safe to draw your stored reserve down as low as in the case of an irrigation supply. The acreage originally planned to be irrigated under the High Line Ditch was about 85,000. My last information is that there are about 20 to 25 thousand acres cultivated under the system. If the water supply were now made adequate it would induce the cultivation of the remaining land.

The present day value of the property of the D. U. W. Co. is about $16,000,000.

Recross-examination by Mr. Nye:

The only means of measurement of the water supply from the Cherry Creek and Miss. St. galleries is at the Capitol Hill Reservoir and at the West Denver reservoir.

425 It is my personal opinion that a direct flow right is limited to the season of growing crops, which is particularly stated as from April 1, to November 1. The Bergen Ditch is not included in the valuation of the plant. Harriman Lake structures are included but not the water right. Sullivan Reservoir is included. It is not in use. The strong Reservoir site is included. It is not in use. The Archer lake lands are included but the power right is given no separate value. It is reflected in the valuation of the other water rights, of which it is protective. The pumps at Platte Canon are included in the valuation. They have been used occasionally.

I think the valuation on this property that is not used but may be useful in the future, and the valuation on the property occasionally used is properly included in the rating base. The water power pumps at West Denver are included because they are used and useful.

Redirect examination by Mr. Dorsey:

No considerable amount of property not now actually used for the purpose of water supply is included in the rating base and none which I do not think will be useful in the reasonably near future.

Harriman Lake has some influence upon the water supply of the D. U. W. Co. for domestic purposes being filled first through Harriman Ditch from Bear Creek, it thereby leaves the ditch free through the rest of the season to furnish the water for city use. About 35 per cent of the water pumped at the West Denver station during the past several years has been pumped by the water power pumps.

Recross-examination by Mr. Nye:

The abandoned property listed at pages 99-100 in Exhibit C. is not included in the rating base. I include such property in the rating base as will be useful in the near future because I believe it is advisable to acquire such property reasonably well in advance of its need.

Witness GEORGE W. SKOULAND.

Direct examination by Mr. Dorsey:

Am assistant to the President and to the Chairman of the Board of Directors of the D. U. W. Co. Been in the service of the company 5½ years. Am familiar with the company's plant and methods of operation. Conduits Nos. 1 and 3 delivering water to Ashland Avenue Reservoir, discharge into wells at the bottom of the
426 reservoir and directly against its head, except to the extent that water is withdrawn from the conduits through a large number of connections before they reach the reservoir. Conduits Nos. 2, 5 and 6, discharge into the Capitol Hill Reservoir over weirs located approximately at the high water level of the reservoirs, except to the extent that water is withdrawn from conduits 2 and 6 through a large number of connections before it reaches the reservoir. Conduit No. 5, discharges directly into the reservoir at all times with no connections to the system. Conduit No. 4 discharges into the West Denver reservoir constantly over a weir at high water level. The assumed high water level at the Capitol Hill Reservoir is at elevation 233 feet. The assumed high water level at Ashland reservoir is at contour 247. The discharge level would vary in the Ashland Ave. reservoir with the head of water in storage. While the discharge level at Capitol Hill reservoir is constant, determined by the weirs.

Practically the high point of the gravity service on the Capitol Hill side is at elevation 120, exceeding that a few feet in certain sections where it is not practical to pipe exactly to the contour. The

elevation of full reservoir at Capitol Hill is 223 feet above city datum which leaves roughly speaking 103 feet head of water on the head of service. If the reservoir be drawn down to the bottom the head would be approximately 80 feet. The high point of the Ashland Ave. gravity service is practically at contour 140. High water in the reservoir is approximately elevation 247. Roughly speaking the head on the gravity service with the reservoir full is 107 feet, and when drawn down to the bottom about 89 or 90 feet.

That head would be available above the high point of the gravity services less frictional loss between the reservoir and point of delivery. Drawing the water down to the bottom of the reservoir simply reduces the pressure at the point of delivery. I have examined the books of record of the D. U. W. Co. and its predecessors to ascertain the conditions under which water has been furnished the consumers in the city of Denver. Exhibit A.34 consisting of 14 sheets contains the license forms used by the various companies from 1872 to date. Offered and admitted. I have also examined the records to ascertain the rules and regulations promulgated by these companies and referred to in the licenses. Exhibit A.35 is a copy of the rules and regulations of the D. U. W. Co. This copy was published in 1898. The same rules have been — effect since the organization of the company. Offered and admitted. Exhibit A.36 contains copies of two sets of rules promulgated by the Denver Water Company. One published in 1887, the other published in 1890. There is a slight difference in one paragraph. Offered and admitted.

427 Exhibit A.37 is a copy of the rules and regulations of the Beaver Brook Water Company and the Mountain Water Company. Date of publication not given. Offered and admitted.

I have made an investigation to determine what portion of the water supply of the D. U. W. Co. measured as part of the total supply furnished by the company is used by consumers outside of the City and County of Denver. From the record of tap openings to consumers' services I ascertained the extent of the openings through which water is delivered for various purposes within and without the city limits, and the relationship between the area of the taps outside and the taps inside of the city limits. I found that 3.8 per cent of the total tap area of the system is located outside of the city limits. In this computation, I considered only the openings to domestic consumers, exclusive of fire hydrant openings. Had the fire hydrant openings been considered there would be less than ½ of one per cent of the total tap area outside of the city. I also investigated to ascertain the percentage of the gross revenue derived from consumers, for water furnished inside and outside the city limits. 2.06 per cent of the total revenue is derived from consumers outside of the city limits. The water company now and for a long term of years past has furnished large quantities of water free to the city of Denver. It does not now nor has it in the past furnished free water outside of the city. I was connected with the company in May 1910. Exhibit A.38 is a copy of a proposed franchise submitted to be voted upon at the City election in May 1910. It was defeated. Exhibit A.38 offered and rejected. At the same election Section 264A of the

city charter was voted upon and adopted. Exhibit A.39 is a copy of a letter to the D. U. W. Co. from the Public Utilities Commission making tender of payment of $7,000,000 for the property of the company as provided for under Section 264A. of the charter. Offered and admitted. Exhibit A.40 is a copy of a letter from the D. U. W. Co. to the Public Utilities Commission declining the tender of $7,000,000 made in Exhibit A.39. Offered and admitted.

Exhibit A.41 is a copy of a letter dated June 25, 1910 from the Public Utilities commission to the D. U. W. Co. asking for certain information concerning the plant of the company. Offered and admitted.

Exhibit A.42 is a copy of the answer of the D. U. W. Co. to the letter of the Public Utilities Commission which is Exhibit A.41. Exhibit A.42 offered and admitted. The Public Utilities Commission did not avail itself of the offer of the company contained in exhibit A.42 relative to an inspection of the company's plant. Exhibit A.43 offered and admitted. Exhibit A.44 is a copy of a letter dated July 25, 1910 from the D. U. W. Co. to the Public
428 Utilities Commission offering under certain conditions to allow Hiram Phillips, consulting engineer, to make an inspection of the plant. Neither Mr. Phillips nor the commission acting through him took advantage of the offer. There was an election on September 6, 1910 at which was submitted the question of issuing $8,000,000 of bonds under the terms expressed in Section 264-*a* of the Charter. Prior to the election Mr. Phillips and Mr. Fellows visited certain parts of the plant and looked them over briefly. They did not have access to any records or plans. There was no further communication concerning this matter with officials of the company. Had there been I think I would have known about it.

Prior to the bond election in Sept. 1910 application for an injunction to restrain the election was made in the United States District Court, by the trustee under the company's mortgage. That is the litigation finally terminated by the decision of the Supreme Court of the United States in May 1913. The suit was instituted about Sept. 2, or 3, 1910. The court declined to enjoin the holding of the election but after the election enjoined the issue of the bonds. Up to the time of the injunction no examination of the plant of the company had been made by or on behalf of the Utilities Commission. Nor was any such examination made up to May 1913 when the decision of the Supreme Court of the United States was announced, except as different members of the Utilities commission appeared on different parts of the plant at different times but no detailed examination was made, nor did they in that period have access to the engineering records of the company. Exhibit A.45 is a pamphlet containing copies of a number of letters which passed between the D. U. W. Co. and the Public Utilities Commission on the respective dates indicated. Exhibits A.44, and A.45 offered and admitted. Exhibit A. 46 is a copy of a letter dated July 26, 1913, from the Public Utilities commission to the D. U. W. Co. requesting to know by what right the company was charging the rates embodied in the leaflet schedule. Offered and admitted. Exhibit A.47 is a copy of the

company's reply to exhibit A.46 in which was included a copy of the leaflet schedule of rates, the schedule under which the company is now operating, and offered to give the commission access to its property and income records to enable it to determine the fairness of the then existing rates. The Public Utilities Commission did not as a reslt of that tender avail itself of the offer of the company. Exhibit A. 47 offered and admitted. About two weeks prior to the receipt of that letter the Utilities Commission appointed a committee of engineers, consisting of Mr. Fellows, Mr. Van Diest and Mr. Allen,
to make a valuation and report on the property of the com-
429 pany. The committee continued its work through the fall of 1913 and made its report in Jan. 1914 as referred and quoted from in the bill of complaint of this case. Exhibit A. 48 is a copy of a proposal for a contract between the City and County of Denver and the D. U. W. Co. prepared and submitted by the Retail Association of the Chamber of Commerce and voted upon and defeated Feb. 17, 1914. The proposal was made public sometime in December 1913. Exhibit A. 48 offered and admitted. I am familiar with ordinance No. 26 series of 1914 of the City and County of Denver, by which the attempted reduction of rates is made which is in litigation in this suit. It came to a city council by virtue of the initiative provisions of the charter. Our first knowledge of the circulation of petitions for the initiation of the ordinance was about Jan. 16, 1914.

The petition was filed with the city clerk Feb. 9, 1914. It contained 5, 593 names. In conformity with the provisions of the charter the Elections Commission certified that the petitions were proper in form and contained the requisite number of signatures. The ordinance was introduced in the Council Feb. 24, 1914, published the first time in the Denver Times, March 2, 1914, passed by the Council and signed by the Mayor, March 3d. No hearings were held by the Council in respect to the ordinance. The D. U. W. Co. was not notified by the Council of the pendency of the ordinance or invited to be present in respect to the matter.

I was present at the session of the Council at which the bill was considered. The only discussion was to the effect that it was obligatory upon the Council to either pass the ordinance or refer it to a vote of the people. There was no discussion of the merits or demerits of the proposition. Neither the Public Utilities Commission nor the City of Denver has availed itself of any of the offers of the company for the sale of its plant or for any arrangement with the company for a definite status in respect to service.

Cross-examination by Mr. Nye:

The suit for injunction brought by the trustee to restrain the bond issue was with the knowledge of the D. U. W. Co. and none of its officials objected to its being brought. The water company refused until the decision of the Supreme Court of the United States in 1913 to recognize the Public Utilities Commission as an official body. And sought to prevent the commission from so acting to the extent that the legal proceedings had that purpose in view. The injunction restrained the commission from taking such action. The

Utilities Commission through the commission of engineers
430 availed itself of the offers of the D. U. W. Co. to permit examination of its property books and records. Exhibit A48 known as the retail plan was not prepared by the water company or at its instigation The company had to do with it after the plan was pretty well along and a committee of the Retail Association sought to consult with them about it.

The water company agreed, if it was adopted, to accept and operate under it. The plan as submitted contained both the suggestions of this committee and the water company to the extent that the opposite sides were willing to accept the suggestions of the other. After the plan was first submitted, officers of the Retail Association requested the water company to agree to modification of it, which it did.

While the plan was being considered the Water company published or caused to be published in the public press, certain advertisements in connection with it. Defendant's exhibits 15 and 16 are two advertisements either published by or paid for by the D. U. W. Co.

Redirect examination by Mr. Dorsey:

My understanding was that the injunction restrained the Public Utilities Commission from taking any action toward the construction of a new plant and I always assumed that they covered all material points relating to the duties of the commission, as against interfering with the enjoyment of the rights of the D. U. W. Co. under ordinance No. 44 of 1890. The modifications in the Retail plan were made at the request of the Retail Association, and the Tax Payers Association which joined the Retail Association in the request. Correspondence passed between the company and the associations in respect to these modifications.

Exhibits A49 and A50 are letters from these associations to the D. U. W. Co. relating to these modifications. Exhibits A49 and A50 offered and rejected. Exception. Exhibit A51 is a copy of the reply of the D. U. W. Co. to Exhibits A49 and A50 agreeing to the acceptance of the suggested changes and modifications in the retail plan. It is a copy of the advertisement identified by me as Defendants Exhibit No. 15. Objection By Mr. Nye to the admission of Exhibits A49, A50, A51, withdrawn and exhibits admitted.

The advertisement identified as Exhibit 16 was not prepared or inserted by the D. U. W. Co. It was prepared by the advertising department of the retail association and states at the top "The Retail Association is solely responsible for the statements made in this advertisement."

431 Recross-examination by Mr. Nye:

The D. U. W. Co. did not know of this advertisement until after it was published. It had no opportunity to approve or disapprove of it until after publication. It disapproved of part of the advertisements that were published. I don't know that this particular one was ever considered. It was never publicly repudiated. The D. U. W. Co. paid for its publication.

The Retail Association had no agreement or undertsanding with the water company as to what it would publish or not publish. The company announced publicly at the beginning of the campaign that it would defray the expenses of the campaign.

Witness GEO. W. SKOULAND Recalled.

Direct examination by Mr. Dorsey:

The relations between the water consumers and the company are initiated by written application of the consumers for service, in which he sets forth the location of the premises, character of service to be rendered and such particulars as are necessary for the purpose of the records of the company. That has been the practice during the life of all the companies that have operated in Denver. Exhibit A61 is the application form used by the D. U. W. Co. and furnished to prospective consumers as the form upon which their application is made. Attached to it is a plumbers application for the service attachment. It is the form that has been used by the D. U. W. Co. since 1894. No attachment by private consumers is permitted without the signing and filing of such an application. The companies operating prior to the D. U. W. Co. required a similar application. There is no substantial difference between this and the forms used by the old companies. Exhibit A61 offered and admitted. On November 1, 1913, there were 44,280 consumers services attached to the system. Of that number 4,790 were turned off because of vacancy or listed upon the company's records as partial vacancies. Today there are 44,723 consumers' services connected with the system and of that number 6,749 are either turned off or partially vacant, an increase in vacancies of roughly speaking of 2,000 over Nov. 1, 1913. The net decrease in the number of consumers served today from the number served Nov. 1, 1913 is approximately 1550. Today means Aug. 31, 1914. For the season beginning May 1, 1914, our total revenues to date are $639,517.50. For the same period in 1913, the revenue from similar sources was $734,634.26 or roughly speaking $65,000 more for the same period this year. This revenue is based upon the leaflet schedule.
432 Reductions have occurred in the revenue on all items except hydrant rentals, miscellaneous revenue and water furnished through meters.

From my knowledge of the company's business It is my judgment that the gross earnings for the year beginning May 1, 1914 and ending Oct. 31, 1913. As / nearly as I can estimate the company be less than the gross revenue for the fiscal year ending Oct. 31, 1913. The taxes of the company will increase for the twelve months May 1, 1914, to April 30, 1915, over the taxes for the fiscal year ending Oct. 31, 1913. As nearly as I can estimate the company will be called upon during that year to pay as much as $120,000 for taxes. It is part of my duty to look after the tax matters of the company.

Cross-examination by Mr. Nye:

The application form Exhibit A61, is the record of the initiation of the relation between the company and the consumer. Whether the business of the consumer was solicited or came voluntarily I do not know, so far as the earlier companies are concerned. The D. U. W. Co. has not solicited business since my connection with it. There is nothing in the record to indicate that it has solicited business or carried on a publicity campaign, calculated to induce people to connect with its system.

It has not done so since my connection with the company. In the past there has been more or less discussion in the public press on the part of physicians and chemists of the question of pollution of surface water in wells and urging the people in sections of the city so supplied to give up that mode of supply and obtain their water from the company. I don't know whether that was at the instigation of the company or not. It was before my connection with. There is nothing in the published articles to indicate who instigated them or what the conditions were or who paid the expenses. There have been many attacks in the form of a campaign against the supply of the D. U. W. Co. as a pure and satisfactory water supply. I have made no inquiries to ascertain whether those attacks through the press have caused any diminution in the number of consumers. The number of services that I testified to as being turned off Nov. 1, 1913, were what we call live services. Completely connected up with the system but simply turned off due to temporary vacancies. Services completely discontinued are cut off at the mains themselves and these are not counted as connections. The revenue figures that I gave on direct are simply the collections from May 1, to Aug. 31, of each of the years including the collections for the half yearly water rates due May 1st of each year. The controversy connected with this litigation probably has something to do with the falling
433 off of collections this year. The 1550 less consumers would hardly produce a difference of $65,000.

Meter rates show an increase of $900 for the period, hydrant rentals about $450, and miscellaneous revenue roughly speaking about 370. Part of the increase in taxes will be due to increased federal taxes and special improvement taxes. My comparison between the year May 1, 1914 to April 30, 1915, with the fiscal year 1913 is a fair comparison, it takes in the complete business of two complete seasons in both cases.

Redirect examination by Mr. Dorsey:

An attack upon the purity of the water supply was one of the issues in the litigation between the city and the company which was begun in 1897 and continued until 1907.

Theoretically the collection of rates from consumers on flat rate schedules and hydrant rentals are made May 1, and Nov. 1, of each year. Those are the dates when the bills come due. Practically the collection is made any time during the six months following the due date. The amount of the rates coming due May 1, is larger than

the amount coming due Nov. 1st because of the irrigation charge for the summer season, which is not made for the winter season.

Recross-examination by Mr. Nye:

The company sometime after the beginning of this litigation agreed because of business conditions to accept monthly payments from water consumers who were unable to pay the full season in advance. This agreement applies more particularly to the small accounts.

Redirect examination by Mr. Dorsey:

The total amount involved on which the time was given on such accounts would probably not exceed $70,000 or $80,000 at the time the arrangement was made. The arrangement was made not because of the pendency of this suit. The effect of that arrangement is not markedly apparent today, because those people are pretty well paid up at this time.

Recross-examination by Mr. Nye:

The figures of collections given are on the basis of 100 per cent of the leaflet rates.

434 Witness CHARLES W. COMSTOCK.

Direct examination by Mr. Dorsey:

I reside in Denver, am a civil engineer. Graduated from the School of Mines in 1890 with the degree of civil engineer 1894 received a degree of Master of Civil Engineering in Cornell University, and in 1898 degree of Ph. D. Since graduation I have followed the profession continuously and exclusively. Have had to do largely with water rights, irrigation projects, and works of that kind since 1888. From April 1909 to April 1913 I was state engineer of Colorado having to do with the administration and distribution of water of the streams in the state. From 1912 to the middle of 1914 I had charge of a large irrigation project in Wyoming. Matters connected with the determination and disposition of water supplies constitute practically the entire duty of the state engineer and his assistants, known as division engineers, of whom there are five, and water commissioners, one for each water district in the state. Appeals from the decision of the water commissioner in any disputed question go to the division engineers and from the division engineers to the state engineer and from there to the courts if anyone remains dissatisfied. State engineer makes reports bi-ennially of the ascertainment of stream flow and other matters pertaining to water supply on the streams in the state.

The experience that I have had has made me familiar with the water supply of the South Platte River and its tributaries, the ditches taking water therefrom and their appropriations and with the extent and value of water rights for irrigation purposes generally in this region. I am acquainted with the property of the D. U. W. Co.

and the S. P. C. & R. Co. and have recently made an investigation of the water rights attached thereto. I have prepared data for the purpose of determining the extent and value of the water rights of Lake Cheesman, which is located on the South Platte River in District No. 23 and is entitled to store water when prior rights situated below it, whose supply is affected by the South Platte River, are satisfied. The water districts below Lake Cheesman in which these rights are located are shown on Exhibit B.

Lake Cheesman has two decrees under which it is entitled to store water. The first of date June 27, 1889, for 30,691 acre feet, the second, Sept. 24, 1893 of 48,373 acre feet. The only storage decree on the South Platte River prior to Lake Cheesman is Barr Lake, situated below Denver whose decree of date Nov. 20, 1885 is for 11,081 acre feet.

There is a small reservoir, Lake George above Lake Cheesman which has a decree for 735 acre feet intervening between the two decrees of Lake Cheesman of date Aug. 31, 1890. It is used
435 for the production of ice so its consumption is inconsiderable. Exhibit A52 consisting of 16 pages of tabular matter contains information as to stream flow in water district No. 8, diversion of water by the ditches in that district, and application of the water diverted. It constitutes part of the data used by me in determining the supply available for storage in Lake Cheesman. The data covers all of the ditches in the district, their appropriations and decrees. The sum total of the decreed amount is 2,109.56 second feet. This represents a larger amount than is to be found in the South Platte above Denver except at very rare intervals. In practice the ditches do not divert anything like the amount of water decreed to them. Tables 2-8 in the exhibits, prepared from the annual reports of the water commissioner of District No. 8, show the annual diversion of water by these ditches for all of the years for which records are obtainable. All of the ditches referred to are for irrigation purposes except where they are noted as for power purposes. In these tables 2-8 are shown the number of days during which water was actually diverted by the ditches and the average quantities taken. By direct irrigation I mean for immediate application of water to the land.

Direct application to the lands is rarely made in the winter season. The records show that the application to direct irrigation under these rights has been confined to a limited portion of the year, approximately 200 days. In table No. 9, a comparison is made of the average diversions for the years for which there are records with the actual diversions in the years 1909 and 1913. These two years being selected because they were years of ample water supply when the actual diversions are presumably all that the ditches require. The total average diversion for all of the years covered by the records of these ditches was 285.13 second feet. In 1909 the actual average diversion by these ditches was 281.25 second feet. In 1913 the actual average diversion was 322 second feet.

From this study I conclude that the demand for water in District

8. bears no relation to the face value of the decrees. Table No. 10. shows that for 23 years District No. 8 has irrigated an average of 18,572 acres and has diverted an average of 76,418 acre feet annually amounting to 4.11 acre feet per acre. The maximum acreage reported was 32,900 in 1913 when 90,360 acre feet were diverted, an average of 2.75 acre feet per acre. It is common talk among irrigators and ditch operators that in this part of the country one acre foot per acre is adequate. The acres irrigated are obtained from the reports of the water commissioners. It is almost invariably reported in excess of the acreage really irrigated. Table No.
436 11 gives a comparison between the quantity of water recorded in the Platte River at South Platte and at Denver. By comparing these gaugings I find an average annual consumption of 76,014 acre feet in District No. 8, neglecting those years in which there was a gain instead of a loss between South Platte and Denver. Table No. 10, from the record of diversion by the ditches showed an average for the 23 years of 76,418 acre feet. The figures are almost exactly the same but do not represent the same thing. The 76,418 acre feet represents an average diversion of water without regard to inflow from any source, but omitting the diversions by the D. U. W. Co. Table No. 11, represents the diversions less the inflow but including the diversions by the D. U. W. Co. In short, the 76,014 acre feet represents the average total consumption of water for all purposes in District No. 8 for 15 years 1899-1913 inclusive. In table No. 11, the quantities by months are dealt with in cubic feet per second. In table No. 12, I show the differences between the discharge of the River at South Platte and at Denver in acre feet. From these studies I have concluded that a mean annual discharge of 75,000 acre feet at Platte Canon or South Platte, together with the accretions to the stream between Platte Canon and Denver will satisfy all demands in District No. 8. District No. 2 is the district lying between Denver and the Cache La Poudre river practically. It is a large district and divided into what is known the upper and lower districts.

In the upper district are twelve important ditches with an aggregate of 1423.68 second feet decreed to them. In the lower district the decreed rights aggregate 1905 second feet or approximately 3300 second feet for the whole district. Table No. 13, Exhibit A52 shows the use of water in upper District No. 2 for the years 1909 to 1912 inclusive. The average number of acres irrigated is 37,179, and the average number of acre feet diverted 135,850, or 3.65 acre feet per acre.

Table No. 14, shows the relationship between the river gaugings at Denver and at Kersey, at the Lower end of District No. 2 prepared for the purpose of arriving at the quantity of water that must be allowed to pass Denver for the benefit of District No. 2. This record extends from 1901-1912 with only partial records for some of the years. The average of the results shows a gain in the river of 223,028 acre feet from Denver to Kersey. Table No. 15, is a computation from table No. 14, to determine the quantity of water added to the river in upper district No. 2, which averages above the mouth

of the St. Vrain, 122,665 acre feet per annum. This is within 13 or 14 thousand acre feet of the total diversion of the upper district.

It is not properly distributed through the district, however,
437 so it is necessary that a larger quantity than the 13 or 14 thousand acre feet be permitted to pass Denver for the benefit of the ditches in the upper District No. 2. To supply the ditches in the upper district that cannot take advantage of these accretions I estimate that an additional 30,000 acre feet must be called for from Platte Canon for the supply of ditches prior to Lake Cheesman. Making a total of 105,000 acre feet necessary to pass the Canon during the irrigating season. Which on the basis of the use indicated by the reports of the division engineer of Division No. 1 for the different months of the season must be divided as follows: May 15%, June 25%, July 25%, August 20% Sept. 10% Oct. 5%.

This places a demand upon the river at Platte Canon in May of 254 second feet, in June 438 second feet, July 423 second feet, August 339 second feet, Sept. 135 second feet, Oct. 85 second feet. During the remainder of the year Lake Cheesman may store so far as the demands in Districts 2 and 8 are concerned. These quantities are sufficient to supply all demand against the stream.

The power rights are satisfied, for their use is a non-consumptive use. Exhibit A53, shows the discharge of the South Platte River at South Platte corrected for the inflow and outflow at Lake Cheesman, prepared from the records of the state engineer's office. Tables cover the period from June 24, 1908 to the end of 1913. From this table using the demands upon the river previously stated I computed the storage available at Lake Cheesman each day. Exhibit A54 shows the quantity in cubic feet per second available for storage in Lake Cheesman form 1900 to 1913 inclusive. Subsequent to June 23, 1908 the corrected tables of discharge at South Platte were used as a basis for this table and prior to that the actual stream flow at South Platte was used. So the results for 1900 to 1907 inclusive show somewhat less storage than would be shown if the corrected tables were available for the entire period. Exhibits A53 and A54 offered and admitted.

I have assumed that Lake Cheesman has the right to one complete filling per year. (Details of storage in Lake Cheesman and quantities available in acre feet over and above the storage from 1900-1914.) Assuming an annual draft on Lake Cheesman of 64,000 acre feet I have concluded from these computations that the reservoir could supply 64,000 acre feet per year clear through to the end of 1914 without shortage in any year and being empty just once at the close of 1904. On the assumption of a continuous draft of 70,000 acre feet there would have been four years in the 13 when the reservoir would not have been able to deliver a full supply. In 1908, 75%, in 1903-4, 85% in 1911, 95%. Dur-
438 ing the other 13 years it could have delivered the full 70,000 acre feet and would not have been empty in any except those four years and would have finished the year 1914 with 27,192 acre feet in storage. On the basis of 70,000 acre feet per annum the

efficiency of the reservoir for the period mentioned would have been slightly less than 88%. And on the basis of its full capacity the efficiency would have been 78%. This period includes the year 1902 which was the year of lowest water supply in the South Platte River of which there is any record, and of which I ever have heard. Lake Cheesman being a stream bed reservoir is capable of utilizing every drop of water that is available for it, having this advantage over reservoirs located off the stream bed. On the basis of 70,000 acre feet annual delivery the water supply of Lake Cheesman is worth $60 per acre foot or for the reservoir, including lands, structures, and water rights, $4,200,000. Which is at the rate of a little more than $50 per acre foot for its total capacity.

The maintenance charges in Lake Cheesman would be practically nothing compared with other reservoirs. There is a ready market and plenty of land in close proximity to Denver for this water at $60 per acre foot. I have made a similar study of the Platte Canon Ditch water rights of the D. U. W. Co. It is my judgment that they would yield 37,670 acre feet per annum for use through Marston Lake. Without interfering with or being interfered with by the storage estimated or Lake Cheesman. There is available also through Marston Lake 6,840 acre feet from Bear Creek making a total from the combination of the Bear Creek and Platte Canon rights of 44,510 acre feet. The value of which is $60 per acre foot or $2,670,600. There are lands available to which these waters could be applied for irrigation purposes, and a demand for the water. I have made no allowance for evaporation in Marston Lake assuming that the purchaser would bear the loss by evaporation and in transit, and the cost of maintaining the works. The figures given include the value of the reservoir and the appurtenant works. In table A52 is listed a priority of the Smith Canal Company aggregating 177.57 second feet, which has been amended, reducing the amount to 57.57 second feet. I am familiar with the water supplies of the D. U. W. Co. obtained through its infiltration galleries. There is a market for the water furnished by these galleries which can be conveniently returned to the river and conveyed to such a point below for diversion as may be found desirable. I consider them worth $60. per acre foot for irrigation purposes. The South Platte River is now over appropriated. A supply of water equivalent to the supply of the D. U. W. Co. for the use of the City of Denver could
439 not be obtained by original appropriation. To reproduce this supply it would be necessary — do so by purchase or condemnation. Even by this means equally good rights for the purpose could not be obtained. Lake Cheesman is the oldest storage right of consequence on the river and the other rights of the Company being perfected for an all year round use demand all of the water available in the stream during the winter months. Assuming, however, that it would be possible by purchase or condemnation to reproduce these rights, the cost would certainly not be less than the value allowed by me for these rights. If water rights were acquired that are now applied to other uses the value of the structures through which they are applied would be destroyed, and compensation would

have to be made for the structures as well as land and water. The value which I have assigned to the water rights of the D. U. W. Co. is for irrigation purposes. They possess a greater value for the purpose to which they now are applied. The value of these rights for domestic purposes is what it would cost to replace them if they were wiped out of existence or if they were devoted to other uses. The people of Denver would be willing to spend whatever it would cost to go two hundred miles to duplicate this supply if it were necessary. It is a very unusual situation to have so large an available supply of water and water rights assembled under one ownership for irrigation or other purposes. In assigning my value I have not added anything for this assembled value.

Cross-examination by Mr. Nye:

I concluded that except under special circumstances the rights in lower district No. 2 would not require water from Platte Canon. Ordinarily the flow below the lower line of upper district No. 2 is sufficient without calling upon any of the later rights of District 8. That condition would not have applied in 1902. I think it would for the greater part of 1904. I did not examine the water commissioner's reports for each of the years, 1900 to 1914 for District No. 2 because I believe that I have sufficient knowledge of the general run of conditions from experience with them to guide me as well as the water commissioner's reports would have guided me. Ordinarily water commissioners call for all of the water they can get. They are not always unbiased state officials. They are working for a particular district as against other districts in many cases. I regard the record of the increased flow of the river through district 2 between Denver and Kersey, which is a net increase over and above all demands averaging more than 200,000 acre feet per annum, as a better guide to whether those ditches were supplied than the
440 report of the water commissioner. If the ditches in District 2 had been short that amount of water could hardly have passed out of the district. That amount accounts for the entire inflow from both tributaries and seepage.

Water commissioners' reports are part of the records of the state engineer's office. They are reasonably reliable. I use them to determine the acreage irrigated and water applied. Those which claim a shortage of water indicate the latest priority supplied. They are the real basis for the operation and administration of the water supply by the state engineer's office.

I have treated the Lake Cheesman rights as being in all respects parallel to a direct flow irrigation right limited only by priority and entitled to all year round storage. In my calculations I adopted as the specific limitation for the irrigation season the period from May 1. to Oct. 31, because it appears to be the actual irrigation season made by the water users themselves. It is the period within which the records show most of the water to have been used for irrigation. Though while I was state engineer water was demanded and accorded to direct flow rights before May 1, and after Oct. 31. In calculating the percentage of water used in District No. 2 I find

that the records of one year show two per cent of the annual use during April. In making up the table in Exhibit A52 I used the actual number of days when water was used in each year in connection with the quantity of water diverted in that year and took the average of the days. I think that in looking into the future that method will be found to produce fair results.

There will be years when the consumption will be greater than the average shown and there will be years when it will be less. The average use for the 22 years by the High Line Ditch was 183.96 second feet, while in 1909, they used 195 second feet. I do not know whether that 195 second feet was its full supply or not. That was my first year as state engineer. I don't remember whether there was a demand for more water than was being received by that company in that year.

If the High Line Ditch was not getting its full demand in 1909 I would not put the calculations against actual results. The calculations are used in the absence of actual results in most cases. I have considered these averages as showing a present limitation of right to demand on the part of these ditches. I do not think the same limitation applies to Lake Cheesman there is a fundamental difference in the situation. Lake Cheesman with a known capacity has stood for years as a notice to subsequent appropriators that the full capacity of the lake can be called upon if needed in any
441 year. It was not within its power to use, or not use as, it might choose, the water, it could only make such use as the demand might come, it could not even create the demand. A ditch diverting water for irrigation purposes can create a demand within certain limits. The owners may bring under cultivation more land. As a matter of fact they use all their efforts in this direction. If after years of effort, 25 as shown in these records, they have reached a limit, I believe that is the limit of what that ditch can have as a right to supply from that time on. I think that otherwise for an indefinite period, perhaps a hundred years hence, no user of water in the South Platte River could rely upon what he could get. If the owners of the ditch do not bring their use of water up to the limit set by their decree, they are at fault. Lake Cheesman as it has been used could not increase the use of water by any efforts it might make. I presume these ditches have a capacity in excess of the average allowed them. I don't think that to the extent of the size of these ditches and physical structures they are equally of notice as Lake Cheesman because they cannot take water unless they can use it immediately. A storage reservoir can take the water when it is entitled to get it.

They are of notice in that respect to the extent of the land to which they can and do supply water, the same as Cheesman. I think that in some instances at least the cultivated area has reached its final limit under those ditches. The High Line for instance. Most ditches divert all of the water they can get and turn back what they don't use through waste ways and tail ditches. In this table of averages, is the element, in some years at least, in the case of the High Line, of absolute inability to get more water. That is compensated

for by other years when they took a great deal more water than they had any use for. The High Line is limited in its contracts for water supply to from 20 to 25 thousand acres. In this average table the year 1902, which was the worst year for all of the ditches, is not included. I have taken into account all of the years for which there are records. I think that is a fairer method than to take any one year or a short period. 1900 was a big year for the river. If the High Line did not get all the water it wanted that year I don't know why. Over 600,000 acre feet of water passed Denver that year and yet the record shows that the High Line only took 68,400. If the High Line was equipped with storage the acreage could be increased to the extent of the storage.

If that water were supplied by Lake Cheesman, the reliability of which I am familiar with I don't think that would increase the direct flow right of the High Line under its decree, I do not think that anything which was done now or which has been done within recent years can entitle the High Line to make increased
442 draft upon the river. I simply use the High Line as an illustration and think that is true of any canal. If the 2109.56 second feet decreed above Denver in District No. 8 were to be supplied it would not be worth while to think of any further use of water. There are relatively few days in the history of the river when that quantity has been available.

Eliminating the power rights from the total amount decreed in District No. 8, there remains 1,467.75 second feet of decreed rights to the ditches listed in Table 9 which by the method of averaging used has been reduced to a total average use of 283.12 second feet. The basis of the reduction really amounts to a failure to use up to the original decree. The average acreage under irrigation using the 76,418 acre feet of water was 18,572. The acreage irrigated has increased during the latter part of the period from 23,947 in 1905 to 32,900 in 1913, being nearly constant for 1907-8-9-10, at about 26,000 acres. The abrupt increase fom 1910 to 1911 I think was due to use of Antero Water.

Table No. 11 Exhibit A52 deals with the difference in quantity in the South Platte River at South Platte and at Denver. I used it for the purpose of arriving at the total consumption in District No. 8. The record covered 116 months out of which I include 88 in the table because those are the months when the discharge at Denver was less than the discharge at South Platte. In the other months there was an increase in the stream between South Platte and Denver.

Therefore, I eliminated them in order to subject the stream to the severest test possible. Had I included them the demand upon the stream would have been less than the 76,014 acre feet which I derived. The fact that tables 10 and 11 result in practically the same figures cannot be considered in the sense that one result is a check upon the other.

It is not true that my conclusion of 75,000 acre feet required for District No. 8 is based more largely upon table No. 10 than upon the others. I have considered both tables 11 and 12 in arriving

at that conclusion and I think that 75,000 acre feet is a liberal allowance for District No. 8. More than enough in most years. Table No. 13, Exhibit A52 is based upon only four years' record of the ditches in District No. 2. I was unable to obtain additional records when I was working up that data therefore I used what I had at hand. I should have preferred to have as long a record in Dist. No. 2 as I had in Dist. No. 8. The average diversion of water in that period 3.65 acre feet to the acre is about 50% too much. About 2/3 of that would be more than a liberal allowance. The length of ditches used has a bearing upon the quantity of water re-
443 quired. Other things being equal the longer the ditch the greater the loss. So far as I know the practice of the state engineer's office has been to permit each ditch to divert what it demanded up to the limit of its decree in the order of its priority. Character of soil may make a difference in the amount of water required. I don't think the soil in Dist. No. 2 demands more water than in Dist. No. 8. Table No. 14 is made up from gauging measurements. Table No. 15 is a compilation of seepage measurements. I used table No. 15 in my computations because I wanted to get information on upper Dist. No. 2 above the mouth of the St. Vrain. Table No. 15 so far as I know is the only guide to the distribution of the accretion in Dist. 2 along that 52 or 53 miles of river. I have not used it to determine the amount of inflow into the river but to determine simply the proportion which comes into the river above the St. Vrain. I applied the proportions to the entire river flow regardless of what part was surface and what part was seepage flow. And assumed the additions between given points in surface flow were in the same proportions as additions to seepage, that is not as gratuitous an assumption as it seems. Those things are measured out in making seepage measurements as the flow of the tributary stream upon the surface. I should have preferred the records of a gauging station at or near the Mouth of the St. Vrain for a period of years. But in its absence I think this a reasonably good guide. In my direct testimony referring to table No. 13 I selected three ditches. The Farmers and Gard-ners, The Burlington, and Fulton, as the ditches which are most likely to require water coming from above Denver. Those ditches would have less advantage from the return flow. The Fulton and the Burlington have their headgates below the Denver Sewer discharges. In table No. 16 the estimate of the proportion of total seepage inflow into Dist. No. 2 which accrues above the Fulton Ditch, is taken from the seepage measurements at the head of that ditch. From that I concluded that 1/8 of the gain in the river between Denver and Kersey was available above the Fulton Ditch, and was available for the supply of the Fulton Ditch. That accretion would all be available for the Fulton and only part of it for the Burlington and none of it for the Farmers and Gard-ners. I eliminated the Duggan Ditch because it is my understanding that its decree has been transferred to the Burlington.

That table is not based on theory but on years of actual observation. I have not calculated the number of acre feet consumed by the Farmers and Gardeners, the Burlington, Duggan and Fulton ditches

in those four years. The average amount of land irrigated in
444 Dist. No. 2 for the four years was 37,179 acres. I estimated 80,000 acre feet necessary for that acreage, of which the Burlington, Farmers and Gard-ners and the Fulton would divert about ½. I think that is a fair way to determine the amount of water which should be allotted those ditches. I arrived at the percentage diverted each month in Dist. No. 2 from the reports of the division engineer giving the actual monthly diversion in acre feet. In determining the quantities necessary to pass Platte Canon in any given month I applied those percentages to the total quantity assumed to be necessary for the season. I assumed that the same percentage would apply in dist. No. 8 as in Dist. No. 2. The Platte Canon Ditch is included in the quantities estimated. In making these calculations I took into consideration the right of Barr Lake to store through the Burlington Ditch. From these computations I came to the conclusion that Lake Cheesman could store any excess in the river during the irrigating season above the amount which I have allowed for the month in which the storage might occur, and during the non-irrigating season it could store all that came to it. There is sufficient flow in the river below Lake Cheesman to supply the 56 second feet of the Platte Canon ditch about 95 per cent of the time. My estimate of 20 feet for the first appropriation of the Smith Canal coincides with the figures set forth in the supplemental decree recently granted. Exhibit A53. The corrected stream flow of the river at South Platte was made up from the records of the state engineer's office. Table A54 is built up from that and from the figures based on my own estimate of 105,000 acre feet at Platte Canon for the ditches.

The figures in page one column 1 Exhibit A54 show the possible storage in Lake Cheesman for January 1900 in cubic feet per second. That is the total flow of the South fork at Lake Cheesman. To ascertain the acre feet available for each month I multiplied the total second feet for the month by 2. The mean storage for the years 1900 to 1913 was found to be 63,000 acre feet. I found that at the end of 1904 there would still be practically 4,000 acre feet in the reservoir and at all other times more than that and I therefore increased the annual draft to 64,000 thereby emptying the reservoir at the end of 1904 but at no other time. Subsequently I used 70,000 acre feet draft to determine just how much shortage there would be at that rate. I testified that in 1903 and 1904 the reservoir would have delivered 85% of the 70,000 acre feet, in 1908 75% and in 1911, 95% in other years a full supply. The use of the mass diagram or an equivalent method, for determining when the water would be stored
and when it would be drawn, would serve to determine the
445 stage of the reservoir at various periods but would not change the final rseult. For that reason I did not prepare any curve.

I have considered that during the irrigating season storage would be accomplished at times when water was being drawn from the reservoir. In determining the amount left in the reservoir at the end of any calendar year I have taken into consideration the addition from storage during that year. The only water that is considered in the assumed draft is the water which actually belongs to the reservoir. I

have not considered the water that simply passes through it. In my consideration I have not apportioned the discharge over different months but I see no reason why the ration should be any different than the percentages used for irrigation under ditches in Dist. 2 and 8. I considered the evaporation loss on the same basis as loss in transit to be borne by the purchaser. In my determination of value of the water I allowed 2 acre feet at the reservoir for each acre of land to be irrigated.

I have considered the 70,000 acre feet of water in Lake Cheesman as capable of supplying a developed area of 45,000 acres of which not to exceed 80% would be actually under irrigation in any one year. That is, approximately 36,000 acres. That leaves practically 2 acre feet per acre for the land actually irrigated. I have assumed a loss by evaporation and in transit of 25 per cent and a consequent delivery on the land of 1.5 acre feet for each acre of land irrigated. I have considered that the cost per acre of land is the value that I have placed upon Lake Cheesman of $4,200,000 divided by 45,000 or something less than $100 per acre. Transportation and maintenance would be an annual charge. The same treatment would apply whether the water was used as a supplemental supply or a complete supply.

There are enough lands under the High Line ditch to absorb all of the water from Lake Cheesman. I have not determined how many miles water would have to be carried to reach the land capable of absorbing it all. My total valuation of $4,200,000 includes water and structures. I made no segregation between the two. Lands under the High Line Ditch are capable of standing a cost of $60 per acre foot for a water supply. It is not necessary for those lands to construct or acquire an interest in an original main canal, all the construction necessary would be laterals. They could contract the carriage of water in existing canals. I know of transportation contracts as low as 8 cents per acre foot per year and some as high as 25 cents. Lands that I had in mind are practically tributary to Denver. They would be used to raise crops of the higher values.

I have no knowledge of the cost of Lake Cheesman or its
446 structures and have made no estimate on the cost per acre foot of construction compared with other reservoirs. I made no investigation to determine whether there was a contiguous block of 45,000 acres under the main canal of the High Line which could take and use this water. In my treatment of the Platte Canon Ditch rights I included the Bear and Turkey Creek rights and also Marston Lake. The combined winter flow of the Bear and Turkey creek rights would be less than the storage capacity of Marston Lake. In my judgment the entire flow from these two sources could be made available for irrigation. I treated the Platte Canon Ditch as an all-year-round right because it has been so used for about 25 years. I knew that all of the water of the ditch did not belong to the D. U. W. Co., part of it belongs to the Lehow estate and water for 195 acres is also used for irrigation by other parties. I made deductions for those uses. The water used by these other parties is included by me in the winter use of the D. U. W. Co. I regard the Mississippi st. and Platte Canon rights as all year round rights for the same reason as

the Platte Canon Ditch right. I believe that the point of diversion of the Platte Canon gallery rights could be changed to the 60 inch conduit, if desired, by application to the court. And the water used for that conduit if it was in the stream. I would not change the Mississippi Street galleries to a surface diversion if I were trying to utilize that water for irrigation. I did not testify in regard to the Cherry Creek gallery right. I have made no investigation to determine the quantity of water returned to the river through the sewers of Denver as compared to the quantity of water supplied by the D. U. W. Co. at Wynetka. I have made no investigation to determine the accretion to the river in or near Denver as a result of the use of irrigation water in Denver. If there is a return flow it is included in the figures given as accretion to the stream at given points.

In valuing these rights as all-year-round rights I assumed they would be continued as such if their use for domestic supply was discontinued and they were applied strictly to an irrigation supply. Also, that the rights of Lake Cheesman would be continued as they are if used strictly for irrigation. I assumed that these rights could be transferred without respect to any other rights arising by virtue of the method of use in the past.

Redirect examination by Mr. Dorsey:

In consideration of these rights I did not give consideration to the rights in Lower district No. 2 prior in time to the rights of the D. U. W. Co. because I concluded that the river was sufficient normally to supply all such demands with the rights above fully sup-
447 plied. I do not call to mind any specific instance when Lake Cheesman was not allowed to store because of the demand for water by the water commissioner of Dist. No. 2 or otherwise. There may have been such occasion. In speaking of the irrigation season as from May to Oct. I meant the practical irrigation season established by custom and use. The Epperson or Green valley ditch regarding which I was asked on cross examination is a ditch located on the west bank of the Platte river with a capacity of 2¼ second feet which recently received a decree running back many years.

That ditch, though not included in my list, would in no manner affect my conclusions as to these water rights. From my study of the Platte Canon Ditch in relation to the other ditches I am satisfied that it should have had its full appropriation during 95% *cent* of the time. By demand upon the stream I had in mind the total amount of water that might be called for under any reasonable use and within the decreed rights of these various ditches. I have not thought of it as meaning the unsatisfied demand. In eliminating the power rights I did so partly from the fact that the water commissioners did not report the amount of water diverted by these ditches, partly from the fact that the water is not consumed and is available again to supply other ditches, also, from the fact that the water company owns all of the power rights except the Smith Canal Company's ditch and a half interest in the Platte and Denver Ditch, concerning which I understand the company has an agreement with

the city, the owner of the other half, that no portion of its claim will be asserted against the Platte Canon Ditch. The power appropriation for the Petersburg Ditch has not been used since I have had any knowledge of the Platte river. There is another consideration in connection with the water for the Smith Canal Company's ditch, it is diverted by the D. U. W. Co. through Lake Archer, used first at the West side Pumping Station and discharged from the tail race there into the Smith canal.

It is my opinion that the irrigable acreage of lands listed in table one exhibit A52 has been fully developed. It is also my judgment that there has been an excessive taking of water for these lands. The limitation upon the acreage under the High Line canal is the irregularity and lack of dependability of the supply under the direct appropriation of the ditch. The acreage might be very much extended if the Lake Cheesman water rights were available for the use through the ditch. I believe the total irrigable acreage under the High Line is in the neighborhood of 85,000.

448 If any of the ditches having direct flow rights which were compared by me availed themselves of the right to store water for use in the same season, in accordance with the Seven Lakes decision, it would not in any manner affect the conclusions given in my testimony. In the total of 1467.75 second feet brought out by Mr. Nye as the total of the irrigation decrees in District No. 8 1184 second feet of the amount is represented by the decree of the High Line Ditch and 81 second feet by the decree of the Petersburg Ditch. The capacity of the High Line is only about half of its decreed appropriation and of the Petersburg Ditch most of the appropriation is for power purposes which has not been used for years and only 7.6 feet of which decreed for irrigation is in use. There also is included the decree of the Brown Ditch for 16.5 second feet, though since 1889 its diversions have never reached 6 feet average for the reason.

Table No. 10 Exhibit A52 indicates a gradual increase in the acreage irrigated in district No. 8. It does not indicate a corresponding gradual increase in the same proportion of the quantity of water diverted by the ditches. The conclusions spoken of by me as sometimes drawn from seepage data and not sufficiently supported thereby were conclusions of a different character from those which I drew from the seepage data in connection with these water rights. By the seepage measurements we undertake to ascertain what the total gain in the river is in any given distance exclusive of the gain from inflow of the tributaries. When I based my conclusions as to the points where gain is made in Dist. 2 upon seepage measurements, that data afforded the only information about the accretion to the river otherwise than by surface streams flowing into it. Table No. 13 shows the diversion by the Duggan Ditch in 1909-10 and none in 1911-12. If that right has been transferred to the Burlington, then the diversion shown by the Burlington in 1911-12 include- the waters diverted under the Duggan right.

The Platte Canon Ditch could continue to divert 95 per cent of its priorities with storage being made in Lake Cheesman at the rate

which I have assumed. That little storage was possible in Lake Cheesman in 1902 is not remarkable. So far as the records go 1902 is the year of lowest stream flow ever known. Exhibit A54 indicates considerable storage during the irrigation months in most of the other years. If the water furnished by rights of the D. U. W. Co. was used for supplemental supply instead of a complete supply, the number of acre feet per acre required would be less for the supplemental supply. Speaking from my general knowledge of the South Platte River I should say that there is no considerable
449 accumulation of silt in Lake Cheesman. I am of the opinion that the cost of maintenance of Lake Cheesman per acre foot of storage would be less than the average cost of maintenance per acre foot of storage for other reservoirs in Colorado. I did not testify as to the quantity of water available from the Platte Canon infiltration galleries. I may have testified as to its value. I merely suggested that it might be handled through the 60 inch conduit. That is not the only way it could be handled.

There are certain of the other water rights of the D. U. W. Co. regarding which I did not testify because I have not had the time since I began the study to do more than I have done in connection with Lake Cheesman, Platte Canon and the other rights concerning which I did testify.

I think my assumption that one eighth of the total accretion to the Platte river between Denver and Kersey occurs between Denver and the Fulton Ditch is conservative, as is also my estimate of the part of that accretion that would be available for the supply of the ditches between Denver and the Fulton. It allows a sufficient margin of safety so that the ditches below having prior appropriations will be supplied, so far as the river is at any time capable of supplying them.

Recross-examination by Mr. Nye:

In determining the acreage upon which the water diverted from the Platte River was applied, I did not take into consideration the acreage watered through the Epperson Ditch. I think it is true that the City Ditch and the Brown Ditch are now supplying all of the acreage possible. I stated that in my judgment the use of water through these ditches had been excessive, because three acre feet and upwards is an excessive use of water. I know the character of the crops raised under some of these ditches. Under the Nevada there is some garden truck, largely general field crops, under the Epperson mostly garden stuff, celery, etc. I do not know that the Brown Ditch has supplied at times as high as 12 second feet not later than 1912. If it did there must have been others when it supplied less than 5 feet since its average for 1912 is 5.55. It is highly improbable that the amount available in the river that year had anything to do with the amount received. It may have had in some years. I stated concerning Table No. 10 Exhibit A52 that the increase in water diverted by the ditches was not in proportion with the increase in acreage indicated under the ditches. The fluctuation of the stream

has to do with the amount of water diverted by any ditch except the oldest, but in the case referred to the largest diversions are not always in the years in which the water supply was largest. That would not necessarily indicate that the demand in a dry year was the greatest. The water supply in the river and precipitation during the growing season are not always alike. It happens that in 1902, the year of very lowest river we had more than a normal precipitation during the growing season at Denver, also in 1908. Those were the two driest years we know anything about here recently. When there is a great deal of rainfall during the growing season the ditches do not require water regardless of how much water there may be in the river and the land does not require it. The records of decrease in river discharge between south Platte and Denver indicated in table 11, Exhibit A52, are reasonably accurate records. For the year 1904 the total discharge at Denver was 151,714 acre feet. I am not able to say that that was an average year. The mean monthly discharges in second feet at Denver were as follows: Jan. 71, Feb. 72, Mar. 63, Apr. 87, May 357, June. 482, July 351, Aug. 409, Sept. 234, Oct. 153, Nov. 123, Dec. 98. 1906 shows about 1/3 greater discharge. The mean monthly discharge in cubic feet per second at Denver were as follows: Jan. 72, Feb. 79, Mar. 99, Apr. 207, May 644, Jun. 341, July 323, Aug. 303, Sept. 320, Oct. 489, Nov. 597, Dec. no record. The estimated available storage for the six months, May to Oct. inclusive for that year was 123,850 acre feet. Table No. 8, Exhibit A52, shows that for the same year the High Line Canal received only 245 second feet or 80,805 acre feet for the season.

Redirect examination by Mr. Dorsey:

According to the water commissioners' report for 1913 the only year in which the Epperson ditch has been reported, the number of acres irrigated was 50. The inclusion of that acreage in my totals would in no manner affect the conclusions I have drawn or the facts set forth. When I said that the application of water in Dist. No. 8 was excessive, I meant that the diversion was excessive. The table which Mr. Nye asked me to prepare from the records of the state engineer's office containing the inflow and outflow of Lake Cheesman is the record as I found it in that office. I have no personal knowledge on the subject. The figures are reported to the state engineer by the D. U. W. Co. I copied my figures from the cards sent to the state engineer's office by the attendant at Lake Cheesman and bearing his signature.

Recross-examination by Mr. Nye:

The table in which the term excessive use of water was applied did not include the diversions by the D. U. W. Co.

451 Witness A. A. EDWARDS.

Direct examination by Mr. Dorsey:

I have resided in Colorado near Fort Collins for 38 years. My business is Irrigation Manager. Been connected with irrigation enterprises since 1891. With The Water Supply and Storage Company of which I was president and manager for 15 years, with The Mountain Supply Ditch Company of which I was secretary and manager, and the Poudre Valley Reservoir Company of which I was director and president. They are large enterprises. Am familiar with the use and value of water for irrigation purposes. In addition to the projects with which I have been connected I have knowledge of other irrigation enterprises. Have recently given consideration to the extent and value of certain water rights of the D. U. W. Co. particularly those of Lake Cheesman. Have not visited the lake but know its location, its approximate capacity and location on the river with respect to the City of Denver. The elevation of the reservoir and available acreage of land under it has a great deal to do with the value of water for irrigation purposes. Lake Cheesman is far up in the mountains and there are large bodies of land on the Platte water shed adjacent to Denver.

In my judgment the value of the water rights in Lake Cheesman is from $60 to $65 per acre foot. On the efficiency shown by Ex. A31 I think the total capacity 79,064 acre feet could be sold for a minimum of $60 per acre foot. If sold on the basis of 64,000 acre feet average storage per year they would be worth $65 per acre foot for the 64,000 acre feet. On the assumption of 70,000 acre feet delivery over a period of 15 years with shortages in four years, in two of which the delivery would have been 85% and in another 75%, and another 95%, I would consider the water worth on a basis of 70,000 acre feet, $60 per acre foot. In my judgment the value of Lake Cheesman is between $4,000,000 and $4,500,000. A stream bed reservoir, such as Lake Cheesman, possesses advantages over a reservoir not in the stream bed because it has no outlet ditch limitation to interfere with its ability to get water. It also is more economical to maintain. Reservoirs off the stream bed have a good deal more artificial work and necessitate much more protection. There also is an advantage in discharging water into the stream where it is available to all ditches below, while the reservoir off the stream bed must have canals to connect it with the ditches that it is to supply. Also, in the case of the stream bed reservoir located above the ditches there is

no necessity for exchanging water with other appropriators.

452 At the altitude of Lake Cheesman, I would not expect silting to any extent. In fixing the price on Lake Cheesman I assumed that the buyer would purchase a certain capacity of the reservoir and assume his share of expense of maintenance and whatever cost was involved in getting the water to the land. In my judgment the water rights at Marston Lake per acre foot are just as valuable as the Lake Cheesman.

Cross-examination by Mr. Nye:

In fixing this price on the water I have assumed that there was ample raw land needing water to use this total amount. In my judgment the water would sell for the same price as a supplemental supply to land having an insufficient water right. Stored water is more valuable than direct flow water. You can turn it on your land just when you need it and hold it back when you don't need it. I know of sales of stored water in my neighborhood for season delivery at prices ranging from $30 to $100 per million cubic feet. This is in affect a rental value. I know of no sales in our neighborhood of purely reservoir water at prices of from $50 to $55 per acre foot. Our companies are all mutual companies that have constructed their own system and each share of stock participates in whatever the system has each year. The deduction for loss in carriage by the water officials varies from 5 to 10 per cent.

I arrived at my values of $60 to $65 per acre foot by computations based on the market value of the stock in the systems that I am acquainted with. I did not assign a higher value to the water because of its availability to lands near Denver. But I consider that the lands that the Cheesman water would supply are more valuable than the lands in our neighborhood.

I think the fact that Lake Cheesman is constructed in the stream bed makes the water more available than in a plains reservoir. I assigned practically the same values to Marston Lake because it lies above the lands to which it could be applied. I am also assuming that it is a sure filler every year. It cannot be filled as advantageously as a stream bed reservoir. But I assigned the same value assuming that it is certainly filled every year. It has two or three different sources that it can fill from. The water that I testified about as having been sold for season use by the million cubic feet was delivered at the reservoir and the purchaser paid the carrying charge. The carrying charge is from $3 to $5.50 per million cubic feet.

Redirect examination by Mr. Dorsey:

I have a general knowledge that there are large bodies of land adjacent to Denver not now supplied with water, to
453 which this water could be applied. The $30 to $100 per million cubic feet season sale price is really an annual rental price. I only know of one sale at the minimum figure of $30, that was very near the close of the irrigation season when there was scarcely any demand for water. With the exception of that one I have not known of any sales at less than $50 and from that up to $100. The $30 price is equivalent to $1.25 per acre foot per annum and the 100 price to $4.25 per acre foot per annum. There is not nearly as much rental water in our district now as there was formerly because the enterprises that former-y rented water have completed their systems and are applying their water to their own lands.

I do not think that the fact of a reservoir's location on a stream bed adds anything to the acre foot value of the water. There is an

advantage in its being located above the land so the water can be utilized without exchange. Water that is above the land can be applied as it is needed and held back when not needed. Therefore is more available than water from direct decrees or from the system of exchanging with the river as we do. The carriage charge of $5.50 per million cubic feet was imposed by the Poudre Valley Company. Water was carried about 18 miles. A million cubic feet makes approximately 23 acre feet. So the charge is at the rate of about 24¢ per acre foot for the carriage. The $3.00 rate that I mentioned was a special price made to some of the minority stockholders in the original company. That is equivalent to a charge of about 13¢ per acre foot. Marston Lake is smaller than Lake Cheesman. Marston Lake is nearer to Denver than Cheesman, and nearer to some of the lands that could be supplied from either or both reservoirs.

Recross-examination by Mr. Nye:

In estimating those values per acre foot I estimated it on the market value of shares of stock in three irrigation systems. In the North Poudre irrigation company and in the Water Supply and Storage Company the value is $50 per acre foot and in the Larimer and Weld Irragation Company $71.25 per acre foot. The Greeley-Poudre district is in my neighborhood, it has upwards of 125,000 acres not yet supplied with water.

Redirect examination by Mr. Dorsey:

The Greeley-Poudre district lands lie north east of, and above the systems that I testified were now fully developed and supplying their full capacity.

454 Witness DANIEL A. CAMFIELD.

Direct examination by Mr. Dorsey:

I have resided in and about Greeley Colorado for 35 years, am engaged in farming, live stock, irrigation, and other business. Have been interested in irrigation enterprises since 1887. That has been my business almost altogether since 1895. Have been president and manager of companies that have financed and built the works of the Bijou, Queen City, Fort Morgan, Hillrose, North Sterling, Julesburg, Riverside, Montezuma Valley, and the Greeley-Poudre District in Colo. The Eden Valley District in Wyoming, the Las Vegas, in New Mexico, and some other smaller ones. Except the Eden valley, Las Vegas, and Montezuma Valley, they are all located on the South Platte river or its tributaries. Work has consisted of building the ditches and reservoirs that go with the works. They are large enterprises the cost of which has been about 10 or 11 million dollars, involving the construction of very large reservoirs and large and long ditches. This experience has made me familiar with irrigation practices and the value of water rights for irrigation purposes.

I am familiar with lands and water rights in the vicinity of Denver. And with Lake Cheesman. Assuming that the capacity of Lake Cheesman to deliver water is as has been testified to here, 57,016 acre feet per year for last 16 years or 64,000 acre feet per year over a period of 15 years (1900 to 1914) without failure, or 70,000 acre feet per year for all except four years out of 15. It is my judgment that the reservoir would have a value of $60 per acre foot for its full capacity, 79,064 acre feet, cost of maintenance and carriage to be borne by the purchaser. It is my judgment that there is available under that reservoir more than twice enough land to absorb that amount of water. A stream bed reservoir such as lake Cheesman has the advantage of being able to take all the water flowing in the stream to which it is entitled without limitation by the size of inlet ditches, also it has no inlet ditch to maintain. Nine-tenths of the reservoirs in Colo. are plains reservoirs. In my judgment the maintenance cost per acre foot of capacity would be less than 1/10 as much in Lake Cheesman as in the average irrigation reservoir. The fact that that cost must be borne by the purchasers of water would affect the value of water rights in Lake Cheesman. Stored water or water equivalent to stored water is more valuable than water available through direct appropriations because it can be used just when you want it without waste and without regard to the conditions of the stream. Lake
455 Cheesman lies above all of the lands that I had in mind that could be irrigated and its water can be used without the necessity of exchange, which also adds to its value. I am also familiar with Marston Lake and assuming a delivery capacity of 40,000 acre feet per year through that reservoir, it is worth in my judgment, also $60 per acre foot. There is an abundance of land under that reservoir to which that water can be applied, and a market for it deliverable at the lake at the price mentioned.

I have applied the price of $60 per acre foot in the case of Marston Lake, upon its actual deliverable capacity because of the fact that it is a plains reservoir. I assume that the water from Marston Lake would be turned into Bear creek for delivery. The cost of structure involved to accomplish this would in my judgment be about $5,000. There would still be a large amount of land in the vicinity of Denver unsupplied with water after Cheesman and Marston Lakes were both used to their full capacity.

Cross-examination by Mr. Nye:

I visited Marston Lake last Thursday. I have never been at Lake Cheesman but have been above and below it. I arrived at my valuation of $60 per acre foot, partly from my knowledge of the immense amount of land available near Denver on part of which millions of dollars have already been spent and which now have a wholly inadequate water supply, and partly on the selling value of water in other parts of the state and from reservoirs on the same river with subsequent priorities.

Water in the Larimer and Weld systems has been sold at an

average price of $65 to $70 per acre foot evidenced by shares of stock. The stock represents an interest in the capacity of the system. And the water delivered depends upon the amount of water the system can get. I think under ordinary conditions an acre foot of water will supply an acre of land. I assumed that the D. U. W. Co. or its subsidiary company owns this water and that it can in the future be applied to irrigation without regard to the use that was made of it in the past. I assumed that the price of $60 per acre foot gives the purchaser an interest in the structures as well as in the water. There is plenty of land to take the 119 thousand acre feet of the two reservoirs, I should say within an average distance of 25 or 30 miles of Denver. Main canals of other partial supply systems are already constructed for most of these lands. By the term equivalent of storage water I mean water that you could get whenever you wanted. I know of no water under the systems that I have been interested in building, selling at $60 per acre
456 foot. There is no water for sale under these ditches. They are all districts and the districts own the ditches reservoirs, and everything connected with it.

The cost of the works in these districts has been much less than $60 per acre foot but I don't think the cost of the works has any relation to the value of the water. The water under these districts is not as valuable as the water from Lake Cheesman. There is no place in Colorado where the same circumstances exist as in the cases of Cheesman and Marston Lakes. The Larimer and Weld Canal has been in operation since 1880. Rights sold originally under it at $300, I think a few at $250. The price now is $4,000. It has been rising steadily during the 30 years.

Redirect examination by Mr. Dorsey:

I have not visited Lake Cheesman myself but have seen photographs, maps and drawings of the Lake and the dam. Am familiar with works of that kind so am informed from these data as to the nature of the reservoir and the dam creating it. In dealing with the 40,000 acre feet capacity of Marston Lake I assumed that 40,000 acre feet would be deliverable at the lake when required and as required. I didn't mean that that was the storage capacity of the lake. When I stated that the water in the other projects with which I had been connected was not as valuable as the water in Lake Cheesman I based the statement upon the difference in conditions, surrounding the projects. Such as location of the enterprise with reference to water available, location of land with reference to surrounding value, market, etc.

The efficiency of Lake Cheesman is unusual. I believe there is only one reservoir in Colorado that would compare favorably with it and that is Lake Loveland which is about 1/10 as large. I think the Riverside would have the same efficiency. That is a large reservoir too. The efficiency there however has not been determined by the record of such a series of years. This is the first year it ever has been filled to its capacity.

Recross-examination by Mr. Nye:

In fixing the value of $60 per acre foot on these water rights it was my idea that the water might be delivered through several systems. The capacity of the Riverside reservoir is in the neighborhood of 50,000 acre feet, I should say the value per acre foot of its water is about $30.

457 Witness CHARLES F. TEW.

Direct examination by Mr. Dorsey:

I am a lawyer and have resided at Greeley Colo. since 1897. Have been connected in a legal capacity with the construction, acquisition of water supply, etc., of a number of irrigation enterprises, and after construction in the matter of control diversion, storage, and distribution of water supply by means of some of these systems. Among these are the Greeley-Poudre, Riverside, and Bijou, Districts and the Green City and Henrylyn Districts and with the original Antero Reservoir project, and with a number of other minor projects. My connection has been both as counsel and in an executive and administrative capacity. And has required me to investigate and become familiar with water rights, their extent and value and the value of lands, both irrigated and un-irrigated. I am acquainted with and have visited Lake Cheesman and am familiar with the water rights claimed for it.

Assuming that the capacity of Lake Cheesman to deliver water is as has been testified to here, an average of 57,016 acre feet for last sixteen years or 64,000 acre feet over a period of 15 years (1900 to 1914) without failure or 70,000 acre feet per year for all except four years, out of the 15, it is my judgment that the reservoir would have a value of $60 per acre foot, on the basis of 70,000 acre feet or a total gross value of $4,200,000. I think there are available, lands, needing that supply which would take it at that price. A stream bed reservoir has numerous advantages over a plains reservoir. Its cost of maintenance is lower, there is less exposed embankment and it discharges directly into the stream, so the only cost of distribution is the operation of the discharging device from the reservoir to the stream below. Also, its ability to take whatever may be the whim of the stream as to flow, and the fact that its intake never will be out of commission. A large majority of the irrigation reservoirs in Colorado are plains reservoirs. Lake Cheesman is located above all of the lands and all of the ditches to which the water may be supplied so that it can be utilized directly from the reservoir without exchange. This is a marked advantage because it sometimes happens that water in a reservoir which must be made of value by exchange, cannot be so used because of the inadequacy of the flow of the stream with which exchange is to be made. The average cost per acre foot capacity for maintenance of Lake Cheesman would be much less than in connection with the average irrigation reservoir.

I visited Marston Lake, also the property of the D. U. W. Co. As-

suming the ability of that reservoir in conjunction with the
458 Platte Canon and Bear Creek supplies to deliver each year without failure during the irrigating season 40,000 acre feet of water, I would consider that water worth $55 per acre foot. I consider this supply worth less than the Cheesman supply because of the necessity of maintaining intakes, inlet ditches and pipe lines, and also because of the necessity if my understanding is correct for exchange of the water there stored to be utilized on the lands under the High Line Ditch. If the water supply is continued under the same ownership as Lake Cheesman and arrangements are made so it can be run in profitable quantities by exchange at the head of the High Line Ditch during any time of the irrigation season, then the water would be of equal utility and consequently of equal worth with Lake Cheesman.

Cross-examination by Mr. Nye:

In fixing my value of $60 per acre foot, I took into consideration valuations of water supplies in the Cache La Poudre Valley, where the soil conditions are similar and the lands adapted to similar crops. The nearest point of the Henrylyn District is about 23 or 24 miles from Denver. The district is about 20 miles long. The water supply is not sufficient for the land within the district or susceptible to irrigation from its works.

There are approximately 120,000 acres of arable land that can be irrigated from the works of the district which is now equipped with main canals. It is possible by the extension of these works to reach a total of about 200,000 acres. That would require an extension of about 60 miles of main canal. Some of these additional lands have a water right but no water. I believe that the present water rights of the district may serve 30 to 40 thousand acres, about 1/3 or less than 1/3 of the total acreage under the works. In my judgment an acre foot of stored water on the lands under the Henrylyn ditches or under the High Line Canal, will annually serve an acre of land with sufficient water for irrigation. By that I mean an acre foot of water measured at the outlet of Cheesman Dam. I assumed the same duty in my valuation of the Marston Lake rights. By operating Lake Cheesman and Marston Lake together, the stored water in Marston Lake can be made equally as available for irrigation accomplishments as the stored water in Lake Cheesman.

I recognize the difficulties of exchange, for which reason I gave a little less value to the Marston Lake rights, but if they are to be used under one control and together they could be made equally
459 available. I do not know of any stored water sold on the basis of $60 per acre foot. The value in the Biiou district is $35 or $40 and in the Riverside $30. But conditions are not yet so settled in the Riverside that the value per acre foot can be determined by the selling price. There are peculiar conditions there. It would take about three years to bring a new district into a normal state of productivity, with an adequate water supply. The new land would need more water than after it has reached its full state of productivity. There would also be more return to the stream for

the benefit of appropriators below as soon as this water is distributed over the areas mentioned. As soon as that begins it relieves the stream of certain duties below which in turn relieve it above. There is a continuous change in behalf of obtaining water by such a system. That can have but one effect upon these water rights, to make them more valuable. Conditions would be changed from what they are at present. This reservoir is not filled and emptied upon lands in the vicinity of Denver every year, nor does the stream in its upper reaches have the benefit of that return. The return flow from the sewers of Denver is very small compared with the return if 100,000 acre feet from Marston Lake and Cheesman Lake were put entirely upon lands in the vicinity of Denver.

Redirect examination by Mr. Dorsey:

I said on cross examination that I did not know of any reservoir water selling for $60 per acre foot. The rights that I had in mind in arriving at that price were the rights in the Larimer and Weld Canal, combining both storage and direct flow, where the price is something in excess of $70 per acre foot of supply.

Recross-examination by Mr. Nye:

The price that I have quoted for the Larimer and Weld Canal is not the price of land and water combined, it is the price of water alone. Generally the water and land are sold together, but once in a while a water right or reservoir right is sold by one farmer to another without the lands.

Witness THOMAS CHEYNE.

Direct examination by Mr. Dorsey:

I reside in New York City. Am a certified public accountant. I am connected with the firm of Haskins and Sells with headquarters at 30 Broad Street, New York. Have recently made a study of the accounts of the D. U. W. Co. The first of the work was
460 done more than a year ago. At that time I was in Denver about 3 months. I have been here now since the early part of April nearly 5 months. Have been engaged in the practice of certified public accountant since the early part of 1905. I have made investigation of the accounts of various institutions and corporations. Exhibit Z was prepared by me. It shows the cost of additions to the system of the D. U. W. Co. from the 1907 appraisal to March 31, 1914. The data is obtained from the original sources of information. The items are properly and correctly charged as cost of additions, extensions and betterments to the property. The figures in red are credits to the accounts or deductions from the items in black. Exhibit Z offered and admitted. Exhibit A55 shows the cost of additions, extensions, and betterments to the property of the D. U. W. Co. from Oct. 18, 1894, when the company was formed to March 31, 1914, by years. The facts set forth are obtained from the original sources of information and represent the

actual cost of labor and material as shown by the original vouchers.

There is included an item of interest on a small portion of the work. In general there is no interest charged on the work. This interest charge amounts to $79,219.14 and was made on the work of the South Platte Canal and Reservoir Co. during the years of 1900 to 1903. The expense of engineering and superintendence is distributed over the accounts each year, and is so included, except for the first five months of the fiscal year of 1914, which is shown in a separate item not yet distributed. I have been unable to ascertain the cost of construction prior to the formation of the D. U. W. Co. for the reason that the books of the predecessor companies that we have do not show those costs. Offered and admitted. Exhibit A56 shows the earnings and operating expenses of the D. U. W. Co. for the 19 years ending Oct. 31, 1913 as shown by the original sources of information in the records of the company. The figures in red signify credits or deductions from the figures in black. Offered and admitted.

The total expenditures for construction shown by Exhibit A55 are $6,034,434.51. Of this item the sum of $697,700.16 is the portion of office, legal and general expense charged to construction during the period of 19 years and 5 months. It amounts to 11.6% of the total expenditure. There is no charge in Exhibit A55 for development expense. The item of surveys represents the cost of surveys for new work where the construction work has not yet been done. Exhibit A56 states accurately the total gross earnings of the company in each of the 19 years. The items charged as
461 operating expenses are in my judgment properly and fairly charged as such operating expenses. Exhibit A57 shows on the basis of the business of the fiscal year of the company ending Oct. 31, 1913 the effect upon its earnings of the application of the rate reduction ordinance. The application of these rates would have caused a reduction in the gross earnings of the company of $279,950.19 or if the schedule had been — effect, the gross earnings would have been $1,074,292.14 instead of $1,354,242.23 as they were under the leaflet schedule.

Exhibit A57 is prepared as an estimate of the business of the company for the year beginning May 1, 1914, ending April 30, 1915, on the assumption that the volume of business will be the same as for the fiscal year ending Oct. 31, 1913. In the treatment of certain items of operating expense. I have assumed that the expenses would be less than for the fiscal year ending Oct. 31, 1913. The item of legal expense in the estimate has been reduced from $45,000 to $25,000. The item of general expense has been reduced from $22,480.60 to $20,000 because I regarded the twelve months beginning May 1, 1914 as a normal period both as to legal and general expense. The estimate shows total operating expense of $333,045.06. Taxes are estimated at $120,000 because of increases due to changes in levies. The decrease in net earnings, as shown by this statement, if the rates fixed by the reduction ordinance are applied, would amount to $263,606.21.

The estimated net earnings for the 12 months period beginning

May 1, 1914, under the application of the new ordinance rates are, $640,342.65 from which is deducted an allowance of $170,000 for depreciation, leaving actual net earnings $470,342.65 also shown by the statement. Offered and admitted.

Exhibit A58 is a statement of the actual business of the D. U. W. Co. for the six months ending Apr. 30, 1914 compared with a corresponding six months period ending April 30, 1913. In the figures for the period ending Apr. 30, 1914, the item of $14,513.52 charged to loss and damage contains the cost overcoming the damage due to the heavy snow storm of December last. Exhibit A59 shows the approximate cost of the money realized by the D. U. W. Co. from the sale of bonds of the S. P. C. & R. Co. during the years 1905 to 1912 inclusive. Taking into consideration the discount and commission on bonds. It shows the amount of bonds sold each year, the net amount of money obtained for them, the normal rate of interest, and the actual rate of interest based upon the sum realized from the sale of the bonds. The final result shows that the company sold $2,923,000 par value of the bonds for which it received $2,592,387 which is equivalent to 88.7% par value. The actual average
462 rate that the company paid for the money represented by the proceeds from the sale of those bonds is 6.12% which includes a sinking fund charge to pay the discount at maturity which amounted at 5% to .478%. In the years 1901 to 1903 the D. U. W. Co. sold $1,000,000 par value of its own bonds from which it derived $963,750, equivalent to 96.4% par value.

The actual cost to the company of the money represented by the proceeds of these bonds is 5.41% and the actual cost of the money derived from the sale of both classes of bonds is 5.95% Exhibit A60 is a table showing the approximate cost of money borrowed by the D. U. W. Co. on notes during the years 1898 to 1908 inclusive. The amount of the loans, commissions and interest paid. The totals of the statements show that the company in that period borrowed $3,225,000 and that the interest rate on the loans was at the rate of 7.26% per annum.

Cross-examination by Mr. Nye:

Construction items shown by Exhibit A55 are listed there in practically the same manner as on the company's books. My reference was more to the vouchers and job orders for descriptions, but they agree substantially with the company's books. The voucher shows the job, in addition to which they have a description of the job which enables us to find out what the application of the particular expenditure was. I also obtained information concerning these items from different employes and officials of the company for the purpose of ascertaining whether the particular items were additions, extensions, or betterments as distinguished from mere replacements or repair. After obtaining this information I used my own judgment as to classification. I was unable to ascertain from the books of predecessor companies whether items charged as betterments were replacements or repairs to property obtained from those companies because such books as we have those companies do not disclose the

details of their construction. I do not know whether the item of $232,954.26 for Marston Reservoir constitutes the total cost of that reservoir or whether expense was incurred in connection with it prior to the obtaining of the property by the company.

The item Pumping Works, Capitol Hill, $17,625.21 in 1895 represents the installation of a new pump, an additional pump as I understand it. Item of $150,000 in 1899 for S. P. C. & R. Co. was for the purchase of that company's capital stock from the Mountain Works Construction Co. The money was paid for it. The item Filter Beds, Mississippi Street, was putting in some new
463 equipment in conection with those beds. The item in 1898 was in connection with the same job. The item, Third conduit, was for the initial construction.

The items in 1901-1904, Filter Beds, cover the total expense in connection with the slow sand filters. The item, Lowering Second Conduit, in 1902 $1,474.67 is properly a construction item, it was an adjustment of the system to meet changes of street grades and the cost about equals the cost of extra excavation, if the pipe had been laid deeper at first. The item of $9,777.39 for the University Park Tank, was for moving and placing the tank in another locality with such additions and connections as were necessary. The item West Denver works $32,822.77 was the construction of the Boiler house and enlargement of the barn at West Denver. The item, Improvements, Ashland Avenue works, $51,494.57 was the installation of the new Worthington pump, stack and additions to the boilers, steel tank and new building. That was an entirely new installation. The item, Capitol Hill Reservoir, $175,060.22 was for the construction of Capitol Hill Reservoir No. 2. Item, Cherry Creek Conduit, was for a new conduit in a different location than the one there previously. I think the account would be entitled to credit for the cost of the former conduit abandoned. I could not determine the amount of that. The item, First Conduit Extension, was a connection between Conduit No. 3 and Conduit No. 1, entirely new construction.

The item, Betterment University Park works, was an addition to the pump house, a new stack, and a boiler feed pump. The item, Improvements, Platte Canon Filter, was a 16 inch connection from the 7th conduit, a chloride house and a floor put in the alum house that previously had no floor. I think it is all properly new construction. Improvements Marston Lake Filers, $475 was a new chloride house. New construction. Improvements, Second Conduit was putting in a 34 inch steel pipe to replace 34 inch wooden pipe, formerly there. That was a partial replacement. I could not ascertain the cost of the property replaced, so on account of the small size of the item I included it. The amount was $6,942.36.

The next item, Betterments Capitol Hill Pumping works, was a rearrangement of some equipment in the station and the allowance was for the additional pipe necessary. I consider it a proper construction item. The next item, Third conduit, was for laying some 42 inch pipe, purchasing a right of way, and constructing a fence, probably on the right of way. The cast iron pipe took the place of

a 40 inch wood pipe. There should be an allowance there for the value of the pipe replaced. I did not know what allowance I could make. The next item, Improvements at Marston Lake, was the building of a new inlet and bridge to the flume. The old inlet
464 probably was not adequate. I called it betterments with the understanding that it was a new inlet. The item, Surveys, covers the charges made for that work in connection with projected work, some of which has been constructed but the charge not carried, to the construction account. Some of it is surveys for projected work that has not been constructed. Miscellaneous, covers some small unclassified items. I could not say it was purchasing property. Next item, is Discount and expense on Bonds sold. Amount shown there is $420,719. According to Exhibit A 59 the discount was $366,863. The difference is accounted for by the fact that Exhibit A 59 shows only the discount and does not include the expense of handling. Also, Exhibit A 59 only shows the bond sales up to 1912, there have been some sales in 1913, not included in that.

The item of Interest, is included there because when that item was charged the D. U. W. Co. treated the S. P. C. & R. Co. as a separate corporation and charged interest on construction funds advanced for its benefit. Subsequently the construction work was paid for in the bonds of the S. P. C. & R. Co. and the expense in connection with the handling of the bonds was treated as an item of the D. U. W. Co. and not charged back to the S. P. C. — R. Co. The D. W. U. Co. receives interest on bank balances, but did not receive any interest on balances arising from the sale of bonds for construction purposes. The construction work was done out of current funds before the bonds were sold and when the bonds were sold the proceeds simply reimbursed the company for expenditures. If interest is to be considered at all, the company should be allowed interest for the time they were out of the use of the money so advanced. Exhibit A 55 shows that the total expenditures for construction on Lake Cheesman were $1,107,258.30. I have not seen the contract under which the D. U. W. Co. received the $4,000,000 of bonds of the S. P. C. & R. Co. It is my understanding that the D. U. W. Co. was required to do a certain amount of construction work to be determined between the two companies. In Exhibit A 55 I have not considered any contractual relations between the companies, but have treated the plant as one system and the bonds in effect as though they were treasury bonds of the D. U. W. Co. The charge for engineering and superintendence was distributed among the different accounts, according to the extent of the work. The work was done by regular employes of the company who were on regular salaries, and operating expenses were reduced to the extent that those salaries were charged into construction account. Office, legal and general expenses are similarly divided between the two activities of the company. Some
465 were incurred for operation and some for construction. Operating expenses were reduced to the extent that those items were charged to construction. The charge varies from 10, to 12, and 15 per cent according to the extent of the construction activities.

The actual rate of interest is determined by ascertaining the

actual proceeds from the bonds sold and applying the interest charge on the par value of the bonds to the amount thus found and then ascertainmg by the use of the sinking fund method the additional allowance necessary to make good the discount suffered between the date of sale and the date of maturity of the bonds. The resulting actual rate 5.95% per annum is the actual cost to the company every year for that money. The depreciation allowance in Exhibit A.57. is not my own judgment, but that of the engineers employed by the company. It is made up of an allowance of $140,000 for ordinary depreciation and $30,000 contingent. In this statement the item legal expenses, set down as $25,000 and general expenses, $20,000 are properly chargeable to operating expenses.

Such extraordinary expense as that connected with this rate litigation would also be a proper charge against operating expenses. Exhibit A.58. shows a net decrease in net earnings of about $34,000. for the six months ending Apr. 30, 1914 as compared with the six months ending Apr. 30, 1913. There is a decrease of about $8,000 in gross earnings, an increase of $24,000 in operating expenses and an increase of about $2,000 in taxes.

I have obtained the details of the construction items shown on Exhibit A.55. regarding which inquiry was made. The expenditures in connection with the Mississippi Street galleries were for the grading of the embankment, building a fence and laying a 24 inch tile pipe from the south end of the beds to the river, all new construction. The item of $446.93 in 1898 was for the laying of a cast iron pipe across Lake Archer to replace a wood pipe. To a certain extent this was replacement. The cost of this job is probably four times what it would have been for wood. I made no specific allowance for the replacement. The rest of the item was for building a 40 inch conduit from the West Denver Reservoir along the west side of Lake Archer to a point intersecting the old conduit south of Alameda Ave. including an inlet well at the West Denver reservoir. I do not understand that that was replacement , it was all new work, done in 1906-7-8- and 1911. The item of the Platte Canon pipe line was the cost of a survey for a proposed pipe line from Lake Cheesman to Platte Canon. instead of including it with the other surveys an account was opened for that proposed line.

466 The item entitled Improvements Capitol Hill works, in 1901 was for installing a new surface condenser and pump at the pump station. A complete *now* installation. The expense in 1903 was for the installation of a new Barr pump a complete new installation. In 1907-8-9- for the installation of the new Worthington pump, additional boilers, additions to the engine room and boiler room, a new smoke stack and all necessary connections. None of it was replacement. The item Improvements at Harriman Lake was for additional riprapping and strenghtening the banks, all new construction. I obtained the information from Mr. Hawes and from the job orders.

The item for the Platte Canon Reservoir, 1903-04, covers the construction of the reservoir complete, including site, pipe, lines, bridges, and all the appurtenant works. Also, part of the expense

of constructing Filter Beds, 4, 5, 6. So that my statement that the other item Filter Beds, covered all that construction was not correct. The items, in 1906-7, represent the construction of the power house, installation of machinery, building of the office and cottages, the sewerage, and steam heating systems. These items are all for new construction. They really are not properly classified under the heading Platte Canon Reservoir. But that is the classification they have used for it. The item, Fourth Conduit, represents the surveying and first material purchases for a conduit then called the fourth conduit, which is now known as the 6th Conduit. That was projected in 1906 or 1907 then work was stopped for a year and resumed again in 1909. The charges under the fourth conduit ought to be added to the 6th conduit as now known.

The next item, Betterments of University Park Works, was the enlargement and improving of a Booster station at that point, consisting of the installation of a second hand boiler, a new boiler feed pump, stack, additional suction and discharge pipes, and a new iron clad building. That was all practically new work. There had been a little shed there before, housing a gasoline engine, but it did not amount to anything. I have made no further investigations of the replacement of the wood pipe on conduits Nos. 2 and 3. And have made no allowance in these figures for the replacement. The principal item of the special assessment taxes, was against the old pump station at 15th and Bassett sts. That property has since been sold and the proceeds are credited into this statement in the item of material and property sold, as is also another item in the same year for a storm sewer tax on lots in West Denver. The following year was the 14th St. viaduct tax against lots in Highland park and Cottage Hill, $461.68. The next item in 1905 was $193.95
467 Highlands Sanitary Sewer tax on lots in Cottage Hill. (Detail of other small items of special taxes.)

I have obtained the figures that you requested yesterday showing the amounts of office, general and legal expenses charged to operation, and construction accounts, respectively from 1895-1913. They are detailed on a sheet Marked Defendant's Exhibit 17. It would make no difference in the facts set forth in Exhibit A.59. if the bonds of the S. P. C. & R. Co. were obtained by the D. U. W. Co. on a basis of 80%. The figures there represent the difference between the face of the bonds and what the system or the two companies combined realized for the bonds, which have to be met at maturity at par. I have eliminated entirely in the accounting all inter-company transactions, and consider the two companies entirely as one. And the figures there set forth will be the cost to the system represented by those two companies when the bonds mature.

As I understand the determining of the value of the D. U. W. Co. property for the fixing of rates, it involves all of the property that is used in operation and the property of the S. P. C. & R. Co. is just as much used in the operation of the D. U. W. Co. as the property which it owns itself. And if we had allowed the expenditures of 80 we will say to equal the proceeds derived from the bonds at 80, we would have eliminated from this construction statement all

of the items applicable to the S. P. C. & R. Co. and then they would have been set out on a separate statement, to which would have been added the 20 per cent loss which it suffered by reason of the sale of its bonds at 80 to the D. U. W. Co. So that it is about as broad as it is long, with this exception, that in that case you would have had the discount on the bonds based upon a contract between two allied companies. And in the statement as prepared, you have only charged in the discount that which was actually suffered by the two companies combined in dealing with the public. I examined into the distribution of the bonds and stock of the D. U. W. Co. as distributed at the time of its organization. The distribution is divided into two parts, one to the Citizens' Water Company and the other to two or three men, a bondholders' committee, I understand. The books simply show the distribution of so much in securities for so much property. The cost of property to the D. U. W. Co. would be the securities issued. There are fragmentary records of the securities issued by some of the predecessor companies. The books of some of the predecessor companies cannot be found. As to the million dollars of bonds remaining in the treasury of the D. U. W. Co. at the time of organization they were disposed of and the proceeds used for construction. They were sold in the years 1901-
468 1902-1903. $500,000 par value sold at 95 June 18, 1901. $250,000 par value sold at 97½ Jan. 11, 1902 and $250,000 par value sold at 98 Jan. 15, 1903. The company had previously made the expenditures out of its own funds and reimbursed its treasury by the sale of bonds.

There is no distinction made between bond money and money from operations in the accounting. It is simply carried as cash in the treasury. The income of the company from interest on bank balances was not a considerable item, probably two or three thousand dollars a year. Its bank balances fluctuated considerably. There were times when they got down pretty low. That is when they had to borrow money on notes to help them out. The construction expenditures were always in excess of the proceeds from the sale of bonds. They were constantly drawing upon their income from operation, except just at the time at which they received a lump of money from a sale of bonds. I did not attempt to ascertain the percentage charged to the different accounts for engineering and superintendence. It can be compiled from the accounts, but you cannot turn to any one page of the books and get it. I did determine that the distribution through the different accounts was proper and examined the vouchers to see that the amount in question had been distributed. It was just the ordinary expense of engineering and superintendence accumulated either for a month or a year and then distributed pro-rata to the accounts in the relation that the direct charges to those accounts bore to each other. I made no attempt to ascertain the percentage basis of the distribution. The method of checking that I used is a proper one and commonly used.

Redirect examination by Mr. Dorsey:

Three dividends of 5% each on the par value of its outstanding stock have been declared by the D. U. W. Co. in its history. The cost items for construction shown on Exhibit A.55. were all incurred after the organization of the D. U. W. Co. Oct. 18, 1894. That statement would not show any costs incurred in respect to any of those items prior to Oct. 18, 1894. As to Marston Reservoir, regarding which I was asked on Cross examination, I am informed that a considerable portion of the work had been done prior to Oct. 18, 1894, but there is no record to which I can go to find out what that amounted to.

Assuming that Marston Lake Reservoir was commenced in 1893 the costs for that year and for 1894 up to Oct. 18, would not appear here. The same is true of the mechanical filters and all other items of property constructed prior to that date. I do not know whether there is any other case on the works where the construction
469 accounts overlap as they do on the Platte Canon reservoir and the filter plant, but undoubtedly there are some where the work is closely allied. I understand that Messrs. Metcalf and Anderson in making their valuation, followed each of the separate works apart from the others. If they have done that their classification would be different than in Exhibit A.55. In preparing Exhibit A.55. I have made no deductions for depreciation and no additions for appreciation. The company in its bookkeeping has done neither.

No allowance is made for depreciation in arriving at the net earnings shown in Exhibit A.56. The portion of office, legal and general expense that is chargeable to construction depends entirely upon the company's construction activities. If construction activities are the major activities of the company then most of the charges to this account will be distributed to construction account. It will not exceed 15% of the total expenditures for labor and material for construction. The distribution of that account is not material, however, because if it is not charged to construction it is charged to operation and results in that much greater reduction in net earnings for the year. There were $189,000. of the bonds of the S. P. C. & R. Co. sold by the D. U. W. Co. in 1913 which are not included in Exhibit A59. The average price received for them was about 88.

If the discount on the S. P. C. & R. Co. bonds had been figured at 20% because of an inter-company transaction, it would have increased the total discount that would have been accounted for by two statements necessary in place of Exhibit A59 by about 8.7 cents on the dollar par value of bonds over the discount shown by the system statement as submitted. Exhibit A59 was prepared on a calendar year basis and Exhibit A55 on a fiscal year basis. The special assessment taxes are for improvements to the property and for that reason are properly chargeable to construction account.

Exhibit A58 shows the operations of the company on the basis of the leaflet schedule. In Exhibit A59 only the actual discount on bonds is considered. In Exhibit A55 discount, commissions, and all other expenses incidental to the handling of the bonds are con-

sidered. Exhibit A60 covers all of the note issues made by the D. U. W. Co. during its history.

Recross-examination by Mr. Nye:

I examined the accounts of the company with respect to the payment of dividends in 1905-06 and the dividends were justified by the financial condition of the company. If the S. P. C. & R. Co. was charged with 20% discount on its bonds by virtue of the sale to the water company, and the water company sold them at a price
470 in excess of 80, it would have credited the difference to profit and loss and it would not be a credit to construction account in any way, if the operations of the two companies were entirely separate. In that case the water company would simply have operated as a contractor doing the work.

In considering the items of special assessment I treated them as being upon property used or useful in supplying the City and County of Denver and its inhabitants with water. As to the securities issued by the D. U. W. Co. at the time of its organization I had no means of determining whether or not those securities were disposed of in settlement of actual expenditures of money theretofore made.

It is my recollection that the proposition of sale just offered certain property belonging to a certain company in exchange for certain bonds and stock.

Redirect examination by Mr. Dorsey:

And that is how all these $7,000,000 of bonds originally issued and all of the capital stock of the water company came to go out, in payment for the property acquired in 1894. Both the principal and interest of the bonds of the S. P. C. & R. Co. are guaranteed by the D. U. W. Co.

Witness ADELBERT A. WEILAND.

Direct examination by Mr. Dorsey:

I reside at Pueblo, Colorado. Am a civil engineer. Received my education at the University of Colorado, at Boulder. Have been engaged in engineering work since 1901, when I was Hydrographer for the Arkansas Valley Ditch Association. From 1905 to 1907 was Hydrographer for the United States Geological Survey. In 1907 was employed by the Colorado Fuel & Iron Co. as hydraulic engineer in charge of their water system at Pueblo. Resigned in 1910 to accept the position of Chief Engineer of the Arkansas Valley Ditch Association, which position I now occupy. The Arkansas Valley Ditch Association is an organization of 20 of the largest ditches in the Arkansas Valley extending from Fremont County to the Kansas State line. My chief duties are to look after the flow of the Arkansas river, assist in the distribution of the waters of that river to the various canals and work up all records of stream and ditch flow and look after the engineering matters in connection with liti-

gation affecting the interests of the ditches. That work has
471 made me familiar with the ditches and reservoirs depending upon the Arkansas River for supply, with the regulations and distribution of water to the various appropriations and with the value of water rights in the Arkansas Valley. I am familiar with Lake Cheesman and have visited the reservoir and inspected the dam for the purpose of determining the nature of its construction. A stream bed reservoir, because of its location, can take advantage of the total stream flow, whereas, a reservoir fed by a feeder canal is limited to the capacity of that canal and misses the peaks of many floods.

The cost of operation and maintenance of Lake Cheesman would be much less than the cost of operation and maintenance of most reservoirs. Lake Cheesman is located above the City of Denver and above the intakes of all ditches to which it may be desired to apply water, enabling the natural channel of the stream to be used as a carrier from the reservoir to any ditch selected.

Assuming that the total capacity of Lake Cheesman is 79,064 acre feet and its capacity to deliver water is as has been testified here by one estimate, 57,016 or by another 64,000 acre feet over a period of 15 years (1900 to 1914) without failure or 70,000 acre feet per year for all except four years out of the 15 (of which efficiency 1 yr. 95%, 2 yrs. 85% and 4th year 75%), it is my judgment that on a basis of an average delivery of 60,000 acre feet it is worth at least $65 an acre foot or in the aggregate $3,900,000. I arrive at that judgment by comparison with water right values in the Arkansas Valley at the present time. Taking into consideration that as to some of those water rights the comparison is not a just one because I consider Lake Cheesman a much more valuable proposition than most of the water rights that I have analyzed. Due to the fact that the application of water at the doors of Denver represents a higher utility and higher value than under some of the systems of the Arkansas Valley. Many of these systems are a long distance from any town and from any market. I have made a careful study of the irrigation systems in the Arkansas Valley for another purpose in which I have determined the total value of all of the systems. Also a study of the average diversions of each of the canals and in arriving at my basis per acre foot I have taken the value of each of these propositions after water was applied to it, and deducted from that the value of improvements and of the raw land without water and divided that figure by the average number of acre feet diverted annually. The analysis shows, considering 8 typical canals, some with good and some with indifferent water rights, an average
of $61 an acre foot, based upon the records of actual diversion
472 through these systems. The average annual diversion of water in the Arkansas Valley, considering winter and summer diversions, is 3 acre feet per acre. In my judgment that is more water than is actually needed.

The lowest annual diversion in acre feet per acre is under the Colorado Canal that has its storage in the mountain reservoir known as Twin Lakes, its diversion is 1.34 acre feet per acre. The value per acre foot of the Colorado Canal figures $82.13. I consider that

system to be more nearly comparable with Lake Cheesman than any other in the Arkansas Valley. I consider 2 acre feet per acre sufficient for proper irrigation in the Arkansas Valley. If the diversions were on that basis it would increase the average value of water under these systems from $60 to $90 an acre foot. I stated that the water of Lake Cheesman was worth at least $65 an acre foot but I see no reason why it should not be worth at least as much as the water right that shows the highest value in the Arkansas valley or $82 per acre foot. That is the Colorado Canal, which has the Twin Lakes for storage. The water of Lake Cheesman is available at all times and can be had when most needed. I am assuming that the water of Lake Cheesman can be used on lands in the immediate neighborhood of Denver. That is within 30 or 40 miles. The price that I have applied is the price at the reservoir. Purchaser to pay the cost of transportation and bear the loss in transit. I am familiar with Marston Lake, another reservoir of the D. U. W. Co. Assuming that by the use of the reservoir in conjunction with the Bear Creek and Platte Canon supply, it is capable of delivering 40,000 acre feet during the irrigation season each year, all deliverable as stored water, I would put the same value on the 40,000 acre feet as at Lake Cheesman or $65 per acre foot at the reservoir.

Cross-examination by Mr. Nye:

I did not estimate any duty for the water at Lake Cheesman. But I would say that one and one-half to 1¾ acre feet would produce good results. I assume that the burden of providing a distribution system would be upon the purchaser of the water at the reservoir. I am assuming that there will be customers for all that water, and that the customers would be able to build their own diversion system. I am not familiar with sales of water in the vicinity of Denver. I do know of sales in the Arkansas Valley, and I consider whenever there is a transfer of land at the prices at which land is currently selling that the buyer is actually paying $61 per acre foot for every acre he buys in the Arkansas Valley.

I arrived at these values by ascertaining the value of the works of the irrigation projects, deducting therefrom the value
473 of the raw lands and the improvements on the land which leaves the value due to the application of the water. Into this I divide the total acre feet diverted by the project which gives the value per acre foot. In the case of the Bessemer Canal this value is $57.50 per acre foot. There is no storage connected with this canal. It waters about 20,000 acres. These valuations were not made for the purpose of this case but for the purpose of a proceeding in the Arkansas Valley.

I had charge of the work of valuation for the Arkansas Valley Ditch Association and had such assistants as I needed. It was my report and my determination. The work was started in 1911 and has been kept up to date. I don't think the D. U. W. Co. knew anything about it until just now. In making my determination of values for the waters of Lake Cheesman I assumed a positive annual efficiency of at least 60,000 acre feet and assumed ownership and

control of that water by the D. U. W. Co. If it should appear that the annual efficiency of that structure was only 20,000 acre feet, the water would still be worth $65 per acre foot at least.

As to Marston Lake I assumed a delivery from the reservoir of 40,000 acre feet. I know that the reservoir itself has not that capacity. I assumed that the difference between the capacity of the reservoir and the 40,000 acre feet would come from sources other than the reservoir capacity. I did not assume any value for the land near Denver to which the water would be applied. The values that I fixed in the Arkansas Valley are borne out by actual sales of land. I know also of sales of water independent of land. The water from the Bessemer Canal sells for $110 per share, representing the water for one acre. On the basis of two acre feet actually applied, it makes the value $55 per acre foot. Colorado Canal stock is worth $60 per share for one acre, at an average diversion of 1.34 acre feet, its value per acre foot is $44.80. The High Line stock is worth $900 per share representing 10 acres or $90 per acre. They divert 2½ acre feet and assuming a 2 acre foot application gives $45 a-acre foot. The Fort Lyons Canal stock is $65 a share for 1 acre with a total diversion of 1.87 acre feet and during irrigation of 1.37 acre feet which gives a value per acre foot of $47.50.

Redirect examination by Mr. Dorsey:

The investigation that I made in the Arkansas Valley required me to determine as a matter of my own judgment the value of the land with and without water, and the value of the improvements thereon and the value of the water right itself. It related to the ascertainment of the market value of the various kinds of
474 property. I have no complete or accurate knowledge of the lands in the vicinity of Denver, though I know about them in a general way.

In my judgment irrigated lands in the vicinity of Denver should command a higher value than in the Arkansas valley. In my valuation of the water stored in Lake Cheesman I have included the value of the structures. I valued the property as an entity. The Colorado Canal irrigates an acreage of 56,000 the gross value of the property is $7,000,000. Taking out the value of the lands without water and improvements leaves a net value of $6,060,000. The average annual diversion is 75,000 acre feet, giving the value per acre foot of $82.13.

If anyone were attempting to acquire all of the water rights of the systems concerning which I gave information as to stock value, he could not acquire them by purchasing the stock, but would have to purchase, as well, all of the lands, water, improvements, and physical structures. In the case of the Colorado Canal system he would have to pay the market value, which I gave here, $7,000,000 and not the value of the stock at $60 per share. If he wanted the water only he would be required after making his purchase to take the water from the land and then dispose of the improvements and land without water.

When this was done it would leave a value for the water of $82.13 per acre foot. The lands irrigated by the Colorado Canal, begin about 40 miles east of Pueblo and continue east for about 20 miles.

Witness HENRY P. ELLIS.

Direct examination by Mr. Dorsey:

Have lived in Denver 26 years. My business is loaning money on real estate and mortgages. Have been engaged in that business 27 years. Have loaned money on all kinds of property, town, business and farm property. Loans are made for clients mostly. The prevailing rate of interest on downtown property is 6% on 5 year loans in connection with which is an additional expense of 2% commission and the usual attorneys' fees and recording and abstracting. Such loans are made on a basis not exceeding 50% of the valuation of the property. On residence property some loans are made on a basis of 60 or 70 per cent of value but I do not like to loan over 50%, insurance companies run as low as 33%. The rate of interest is also 6%. The prevailing rate of interest on farm loans is 7%. On farm loans the same margin of security is required as on city property. The borrower pays the commission and expenses. My commission never exceeds 3% on a five year farm loan out of
475 which I take care of my local agent. Some people get higher rates, 7% interest and 3 to 5% commission out of the loan the first year for farm loans. Commission on city loans never exceeds 2%. My business now is about $600,000 a year. It has run as high as $800,000 for the last 17 years. About 17 years ago the interest rates were 8%. At that time farm loans ran from 8 to 10%. Interest rates began to decline in 1897.

Witness JOSEPH C. HOUSTON.

Direct examination by Mr. Dorsey:

Have lived in Denver 26 years. Am asst. cashier of the First National Bank. Have been in the banking business in Denver for 25 years. Am familiar with bank loans, security required, and its extent and relation to the amount of the loan. The prevailing rate of interest on bank loans is about 6½ per cent. We have some loans drawing 7 and 8 per cent and some as low as 5 and 5½ per cent. That average has existed for the last two or three years, but under present conditions it may increase materially in the near future. Banks usually aim to get collateral security of at least twice the amount of a loan. Loans are sometimes made upon personal security with indorsement and also upon the financial standing of the party himself without security. In those cases we figure the quick assets of the borrower against liabilities on the same ratio as collateral security, 2 to 1. The average loan period is 90 days. The average interest rate in 1894 was about 10 per cent. The 6½ per cent rate has been in vogue for the last 5 to 8 years. The decline from 10 per cent in 1894 was a gradual decline. Years back loans were made more upon personal indorsements, no com-

missions are paid by the borrower obtaining loans from the bank. When we can we discount the loan collecting the interest in advance, giving the customer the balance. That makes the actual cost of the money to the customer higher.

Cross-examination by Mr. Nye:

I have not considered the advance interest payment in arriving at the average rate of 6½ per cent. Exhibit A.4 offered and admitted.

In the course of an argument in support of defendants' application for a continuance, Mr. Stevens, City Attorney and of counsel for defendants, said in part:

"Another thing that must be borne in mind in this whole procedure is that it" (the ordinance under attack) "was not
476 an ordinance passed by the city council of the City and County of Denver; it was an ordinance initiated by the people of the City and County of Denver, and the council had only one duty to perform under the charter, and that was to pass it without any question of any kind or character." * * *

Mr. Dorsey: "Do you mean to say that the council of the City and County of Denver passed this ordinance without any determination as to whether it was reasonable or not?"

Mr. Stevens: "Absolutely. They had no discretion in the matter. The charter says that when these measures come before the city council that within a certain time they shall submit them to the people; but this, as I understand it, was initiated and presented to the council under the section which provides that, when presented with the signatures of a sufficient number of the citizens of Denver, it is mandatory upon the council to pass it. In any event, that was the view that the council took of its duties."

By agreement of Counsel Exhibit A.59, withdrawn and a new exhibit A.59, containing information as to bonds of the S. P. C. & R. Co. sold in 1913, admitted in its stead. As the detailed testimony of Mr. Cheyne on that subject.

Witness MILTON SMITH.

Direct examination by Mr. Dorsey:

Am an attorney. For the past 20 years have been associated with irrigation matters in the vicinity of Denver, and very actively since 1900 or 1901, beginning with the investigation of a plan to divert waters from the western slope. In 1902 participated in the organization of the Farmers Reservoir and Irrigation Company for the development of the Standley Lake project. Have had to do not only with the legal work but as a director and officer of the irrigation companies and the companies associated therewith. Am familiar with the value of water rights in the vicinity of Denver and with the lands irrigated and unirrigated, particularly those which are or may be irrigated from the South Platte river with waters available above Denver. I know the location of Lake Cheesman but have never visited the reservoir. Assuming that the actual

capacity of Lake Cheesman is 79,064 acre feet and its capacity to deliver water is as has been testified to here, by one estimate 57,016, annual average 1899 to 1914, or by another 64,000 acre feet, per year, over a period of 15 years without failure, or 70,000 acre feet per year for all except 4 years out of 15 (of which, efficiency
477 1 yr. 95%, 2 yrs. 85% and 1 yr. 75%). It is my judgment that the value of that water is $75 per acre foot for whichever quantity or any of them that experience shows are available for delivery. I would apply the value of $75 per acre foot to the 70,000 acre feet considering that those failures are merely nominal, they amount to nothing. I know where Marston Lake is and what it is. Assuming that by the use of Marston Lake in conjunction with the Bear creek and Platte Canon water rights of the D. U. W. Co. there can be delivered in each irrigation season, 40,000 acre feet in the same manner that stored water is delivered. It is my judgment that the 40,000 acre feet are worth $75 per acre foot the same as Lake Cheesman. It does not make any difference whether the capacity of Marston Lake is acutally 40,000 acre feet if in the practical operation of it there can be delivered through it or by means of it 40,000 acre feet of water. There is sufficient land in the vicinity of Denver now unsupplied or inadequately supplied with water to use many times the quantity of water available from these reserviors. As a matter of fact, the Farmers Reservoir and Irrigation Company could use every acre foot of it through canals which they now have constructed to supply lands under the canals which at this time have no water.

These are not the only structures through which the water could be used. The High Line Ditch could use it.

Cross-examination by Mr. Nye:

The average duty that I would assign to this water is 1 acre foot per acre. Some time ago I tried to buy water for a farm near Loveland which was quoted at $75 per acre foot and when I went back to get it it had been sold. I have heard of a great many sales at that price, but have not participted in any. The selling price of water in the Standley Lake system is $50 an acre foot. The system is running water and selling water rights. The sales are on an acre foot basis. One share of stock is entitled to its pro rata share of our supply up to 10 acre feet, the price per share is $500. The price assigned is the price at the reservoir, consumer to pay the carrying charges. The loss in transit between Lake Cheesman and Denver would be comparatively small.

There would not be the slighest trouble in disposing of these water rights. The farmers would all jump at the proposition of getting water out of Lake Cheesman. I have included in the price of $75 per acre foot the fact that the structures are there to retain and store the water. The water possesses that value for irrigation purposes. I have not considered any element of value be-
478 cause of its being used or useful as a domestic supply. Essentially this water would be worth as much to the farmer operating near Fort Morgan as to the farmer operating near

Brighton. There might be a slight difference but not much. One element would be slightly more loss in transit, and the other a question of the return which the farmer would get from his crops that far from Denver, but that is not very much. I eliminated the cost of carriage practically because I think the water is worth that at the reservoir. The route of carriage from Cheesman Lake to Fort Morgan is through the channel of the South Platte River. There isn't very much cost to that or very much loss either but there is some. The loss is also small as compared with what he wastes under the present system of farming and if he saw an opportunity to get this class of water he would jump at it in a minute if he wanted water.

I don't think the loss between the outlet of Lake Cheesman and the head of the Fort Morgan canal would exceed 3% during the irrigating season. I know that that disagrees with some engineers and with the state authorities, but theory is one thing and practice another, and when you have observed it for a number of years, nine times out of ten it safter to go on practice. In my judgment the practice is that you wouldn't lose more than that unless somebody stole your water. I think it is a fact that the state authorities always charge more than 3% loss in the transit of water, I think they run from 5 to 15%.

Redirect examination by Mr. Dorsey:

I think the water is more valuable for the use to which it is now applied than for use for irrigation. In selling water rights under the Standley Lake system, they have been sold on the basis of delivery in the average season of 210,000 acre feet of water. There are 21,000 shares outstanding, 17,000 shares are definitely fixed to land and 4,000 shares have not yet been sold to individuals. The system has not been in operation for a period of 10 or 15 years so as to have demonstrated that it is capable of supplying that amount of water each year. If it had been I would insist on the price of their water being raised to $750 a share instead of $500.

In a new and untried system you never can get the same price for water as in the system that has been tried for a number of years. So far as the price which I fix is concerned. It is based on the assumption that there has been so much water available for delivery and it has been demonstrated for this number of years, that explains the difference in the value of water in that system and in the Farmers system. In the Standley Lake System, the owner of one share of stock is entitled to an amount of water
479 furnished from all the sources of supply of that system in combination, which is equal to 10/210,000ths of the total not exceeding an allowance to the owner of each share of 10 acre feet in any event.

480 In the District Court of the United States for the District of Colorado.

In Equity. No. 6274.

THE DENVER UNION WATER COMPANY, Plaintiff,
vs.
THE CITY AND COUNTY OF DENVER et al., Defendants.

Abstract of Defendants' Testimony.

JOHN F. HEALY, a witness for the defendants.

Direct examination by Mr. Stevens:

Witness is now and has been chief of fire department since August 1, 1912; has been connected with fire department since September 1, 1894, in various capacities, except for period of about two years, in 1895 and 1896.

During the past summer made special tests of company's plant for determination of fire pressure, and has continually observed pressure in the discharge of his duties.

In June last, in company with Master Mechanic Mason, made pressure tests covering two or three weeks in the month; tests made at hydrants close to hospitals, schools, state institutions and similar places; tests made with pressure gauge; flow pressure taken with Pitot tube.

Hydrant at 19th and Pearl, static pressure 42½ pounds; flow pressure, with one-inch tip, 40 pounds; with one and one-half inch tip, 40 pounds.

481 Witness has attended all fires of any magnitude occurring in city since April 1, 1903.

Knows about the storage systems of the company about the city; has no technical knowledge of source of supply and size of the mains other than that gained from reports of National Board of Fire Underwriters of 1906 and 1910.

(Plaintiff's objection as to opinion of witness on adequate pressures overruled.)

Based upon practice, thinks 100 pounds' pressure in business district and 75 pounds outside would be adequate. Pressure at St. Luke's hospital 42½ pounds; would require total pressure to get the water at the end of a 400-foot fire line with one-inch tip; loss of 10 pounds to 100 feet; requires 43¾ pounds to raise the water 100 feet.

Should have at least 80 pounds pressure at the nozzle.

Plenty of water in the main for more than one fire engine.

Supply of water adequate.

Test at 18th and Franklin, static pressure 30 pounds; flow pressure, with one and one-half inch tip, the same; sufficient volume, but pressure lacking, this demonstrated by the fact that there was no

difference between static and flow pressures; 17th Ave. and Milwaukee, static pressure, 110 pounds, flow pressure with one-inch tip, 80 pounds; pressure adequate, although it dropped to 80 pounds with one-inch tip; 50 pounds with inch and a half tip. 14th and Marion, static pressure, 70 pounds, flow pressure 50 and 35 pounds; 13th and Clarkson (Wolfe Hall) static pressure, 30 pounds, flow pressure 30 pounds.

12th and Clarkson, static pressure 25 pounds, flow pressure 25 pounds.

8th and Pennsylvania, (near Campion and Cheesman residences) static pressure 30 pounds, flow pressure 30 pounds.

1st and Franklin, static pressure 45 pounds, flow pressure 40 pounds.

Warren Ave. and University St., static pressure 25 pounds, flow pressure 20 and 15 pounds.

State Home for Dependent Children, Iliff Ave. and So. Washington, static pressure 25 pounds, flow pressure the same.

At County Hospital, 6th and Cherokee, static pressure 55 pounds, flow pressure the same.

19th and Stout, static pressure 65 pounds, flow pressure 60 pounds.

38th and Boulevard F, static pressure 20 pounds, flow pressure 17 and 15 pounds.

42nd and Lowell Boulevard, static pressure 45 pounds, flow pressure 35 and 25 pounds.

482 38th and Tennyson, static pressure 45 pounds, flow pressure 40 pounds.

West Colfax Ave. and Wolfe, static pressure 30 pounds, flow pressure 25 and 15 pounds.

36th and Gilpin, static pressure 70 pounds, flow pressure 65 pounds.

34th and York, static pressure, 25 pounds, flow pressure 17 and 10 pounds.

12th and Quebec, static pressure 45 pounds, flow 40 and 34 pounds.

Colorado Boulevard and Colfax, static pressure 100 and 25 pounds.

Pressure depends upon gravity.

Witness describes reservoirs and pumping systems which take care of pressure for the city. 100 pounds pressure in business district and 75 pounds pressure outside will take care of fires without question. Knows about pressure in other cities, from reading.

(Objection to testimony by witness as to pressure in other cities overruled.)

Witness informed that Croton system delivers water at top of 10-story building at 85 pounds pressure.

Witness informed that Croton system delivers water at top of 10-story building at 85 pounds pressure.

(Motion to strike not ruled on.)

Says pressure in down-town district received from pumping plant

in West Denver, and there is a loss of from 15 to 20 pounds in district between 16th and 17th Streets from Broadway to the depot, and to secure 100 pounds pressure at that point, would require 115 to 125 pounds at the pumping plant.

Made test at Depot about first of July; hydrants at 16th and Wynkoop and 18th and Wynkoop gave 65 pounds static and flow, showing a large main at that point.

All tests made by witness showing pressure under his estimate of 100 pounds for business district and 75 pounds for outlying district, inadequate for service without fire engine.

Referring to book gotten out by Fire Underwriters, says minimum of 50 pounds pressure at nozzle is necessary.

In instances where tests showed sufficient pressure, flow was short.

Pressure is desirable in fighting fires, to give driving quality to stream; a driving stream is more efficient than one which merely throws water on fire.

If fire can be extinguished at incipiency, less damage is done; hose wagon invariably precedes engine at fire.

There are places in Highlands and South Denver where water supply insufficient for first-size fire engine.

483 On September 28, 1912, at zinc works fire, 800 feet of hose was used on hydrant at Cedar and Broadway, and suction collapsed.

On February 14, 1914, at 1218 Clarkson, extinguished fire with garden hose attached to 250 feet of fire hose.

Adapters are carried to reduce size of stream when necessary, to complete the extinguishment of fires; give better pressure.

In opinion of witness, if company's mains were 8-inch, and water delivered at 10 to 15 pounds static pressure at the hydrant, there would be sufficient water for all fire engines required.

Witness thinks if the mains were 8-, 10-, and 12-inch, and honeycombed together with hydrants on every corner, there would be plenty of water, but would need fire engines.

Difficult to catch fires in incipiency with fire engines.

With fire engine, it requires 15 to 20 minutes to get 100 pounds pressure at the engine.

Cross-examination by Mr. Dorsey:

Witness is a building mechanic; has learned and worked at the plastering trade; knows nothing about the construction and operation of water works systems, except what he has learned in regard to pressures and the kinds of streams required to extinguish fires.

Witness thinks he knows how the pressure is obtained and maintained in water works system.

Says the pressure for entire business district is supplied from West Denver pumping plant, Capitol Hill pressure supplied from reservoir at 11th and Clayton, Montclair by the booster plant at 29th and Albion, and University Park by a booster plant.

Has some doubt whether West Denver pumping plant would maintain pressure without aid from other parts of system; thinks that if

there were enough tanks at 29th and Sheridan Boulevard and larger reservoir at 11th and Clayton, down town pressure could taken care of by valves, and the West Denver plant done away wi

Says Capitol Hill reservoir might have something to do w pressure in down town district, but bases this opinion upon inform tion given by engineer at the West Denver pumping plant and reading Goldsmith's report.

Would not undertake to advise how a plant should be desig to furnish water; does not think the north Denver reservoir is a good; thinks it has nothing to do with the pressure.

484 Ashland Avenue reservoir is much higher than 16th a Arapahoe, and the tanks are higher than the reservoir.

Elevations at different parts of the city vary a great deal.

Witness does not know that the Ashland Avenue reservoir anything to do with the pressure of water in the pipes in the do town district.

Witness does not know how the Capitol Hill reservoirs are c nected up with the system. Does not know whether his duties chief require him to know about the water plant and how it is c nected up; has tried to find out some things in order to ans questions asked by the public; knows more about the plant than previously.

Witness details in general way his knowledge of the system, wh is confined mainly to source of supply.

In estimating 75 pounds pressure for "outside districts" wit means territory east of Broadway, north of Platte river, east of S Street, west of Colfax Avenue; 75 pounds static pressure in th districts would enable department to fight 99 out of every 100 without use of engines.

With 100 pounds static pressure in business district, could out incipient fires without engines; so-called out-side district co country variable in elevation.

Thinks that to maintain 75 pounds pressure at every hydran the territory, it would be necessary to build reservoir in Cla Addition, one in Montclair, South Denver tanks would have t elevated, and something would have to be done on the North S thinks all of Clayton addition and district east of City Park Park Hill could be taken care of by reservoir in neighborhoo Clayton College.

Does not know whether various storage structures would hav be connected up; does not know whether present Capitol Hill r voir is higher than Clayton College; thinks that in such a sy as witness has in mind, 75 pounds pressure should be maintain the low points.

Thinks it is a debatable point whether it would be necessa maintain a pressure higher than 75 pounds at the low poin order to keep a uniform pressure of 75 pounds throughou district; thinks that if the pipes would stand it, a pressure o pounds would do no harm.

Would not know whether it would be possible to mainta pounds pressure in a gravity system uniformly throughout th

side districts; would know nothing about designing such a system or constructing it. When asked if, in the present system, a pressure of 75 pounds were maintained at the Capitol Hill reservoir, there would not be a much greater pressure at Broadway, witness expressed opinion that there would be if there were not a number of outlets to diminish the pressure. Can give no idea what it would
485 be; does not think high pressure would interfere with plumbing for domestic uses.

Has knowledge of other cities which he has visited, in additions to reports of their assistant fire chiefs, where city mains carry more than 100 pounds pressure and are used for both domestic and fire-fighting purposes.

Does not know how much greater than 100 pounds ordinary plumbing would stand.

Thinks that when mains are connected together around every block, pressure would equalize itself.

Knows that in New York, Boston and Philadelphia, and a large number of other cities, they have a high-pressure system for fighting fires, and are doing away with fire engines, and maintaining a static pressure of 300 pounds for fire purposes. In all cities where they haven't a separate fire pressure, they use fire engines, although a great many cities have 75 and 100 pounds' pressure. Where engines are used, the question is not so much one of pressure as it is of the volume of water available; the volume of water is the main thing.

Has a big list of fires where there was trouble for lack of water, but there was no blame to the company, because mains were not owned by it. Witness' experience indicates that water company mains are much larger than 6 inches. There are some places where there are long leads of 6-inch pipe that will not supply fire engine, but they are very few, and mostly in outlying districts, and a few dead ends in the business district. Witness knows of but one fire down town where there was trouble with water supply; the incident occurred ten or eleven years ago; there was not water enough in the main for two engines.

Considering the fact that fire engines are used in Denver, and speaking generally of that part of the water system which belongs to The Denver Union Water Company, a satisfactory volume and adequate supply of water for fire purposes is furnished, except in a few instances in outlying districts; fire engines have been used for over twenty years. Should have four hydrants at every street intersection in down-town district.

Would not abandon use of fire engines if pressure was 100 pounds static pressure and 75 pounds static pressure outside. With pressure as it exists, many fires are put out without engines.

Witness describes location of chemical equipment.

The city fire department is too small; is lacking in men, money and apparatus.

The fire loss in Denver in 1913 was $1.12 per capita, which is very low for a city the size of Denver; only one other city that
486 year that was close to it; there have been some bad years. Denver is in third class in rating by insurance companies,

even though the fire loss is small; it has never reached over $600,000 in one year.

The fire loss in 1913 was less than it has been for seven or eight years.

To adequately equip the fire department it would cost $250,000. With a $250,000 investment in the fire department witness would be in as good position to fight fires with present pressures as he would be with the fire department as at present equipped and the static pressures of 100 and 75 pounds, respectively.

Pressure tests testified to were made in the month of June. There were pressures taken in 1906 and 1910 by the Fire Underwriters, and years ago Roberts, who was then chief, maintained a recording gauge. The pressure is now less, generally speaking, than it was when witness entered the fire department.

In former times the pressure was 85 and 90 pounds in the business district, and it is now 65 pounds. These pressures are now less than they were in 1895. Witness took static pressure in Union Pacific shops in 1903, and got as high as 110 pounds; thinks he cannot get that now.

The flow pressure at the depot is 65 pounds.

Witness has testified to all hydrants that were tested in June: witness picked out the locations.

The volume at St. Luke's hospital was adequate.

There are not sufficient hydrants in the city for fire-fighting purposes; there ought to be fifty per cent more. There are several hydrants in the vicinity of St. Luke's; would require about 400 feet of hose, which is the average lead of hose used in the city.

The loss in pressure in the hose would be about 10 pounds to each 100 feet, although the loss is different in different kinds of hose.

All fire apparatus in Denver is up-to-date, but there is a lack of quantity. With 42½ pounds static pressure at the hydrant and 400 feet of line, the pressure of the water at the nozzle should be 20 pounds; that is not adequate to fight fire with; it will throw water probably thirty feet, but the stream is not effective over ten or fifteen feet.

If there were a pressure of 75 pounds, static, at the hydrant, there would be 50 pounds at the nozzle tip, being an effective stream.

Tests were not all made within a week; they were taken whenever witness had a chance.

Does not know when water company had completed repair of June break; witness offers to repeat the tests; made notes of
487 the tests in his book as taken, but did not keep the dates, and does not know just when they were made; the driver or Mr. Mason might know. Witness feels that he did not take any tests while the water company was having trouble with the breaks in question.

The pressure at 8th and Franklin showed adequate volume of water for engine use.

Pressure at 17th and Milwaukee was adequate without an engine, but volume might not be enough with two engines. Made no actual test to determine that point. Hydrant at 14th and Marion might

be adequate, but does not know whether it would furnish 700 gallons a minute, because pressure dropped from 70 to 35 pounds.

The engineers are instructed to furnish 100 pounds pressure as a regular matter, at which rate they would take 400 gallons a minute from the hydrant. During 20 years' experience, witness has found no failure of volume, except in one instance.

Wolcott school test was made in the afternoon, but witness cannot state the date; at 13th and Clarkson, hydrant was sufficient in volume and pressure for fire-engine use; the same was true at 12th and Clarkson, and 8th and Pennsylvania and at 1st Avenue and Franklin.

The hydrant tested at Warren Ave. and University Street is colored green on the map, Exhibit A. At that point there was a static pressure of 25 pounds, a flow pressure of 20 and 15 pounds. The test at So. Washington and Iliff Street showed adequate volume and pressure for fire-engine use.

The hydrant at 6th Ave. and Cherokee, adequate in volume and pressure for fire-engine purposes; so also was hydrant at California and 19th.

Does not know other pressures at 19th and California; made some tests near depot, showing static pressure of 65 pounds, flow pressure the same.

The static pressure at depot and at 19th and California was the same; the hydrant on Boulevard F is located on the east side, on the northeast corner of 37th Avenue and on high ground.

Made tests at St. Vincent's Orphanage, on the west side of Boulevard F, at which point the pressure was greater; the hydrant on Boulevard F gave static pressure of 20 pounds, and flow pressure of 17 and 15 pounds.

The pressure at St. Vincent's Orphanage, which is on Lowell Boulevard and 42nd Avenue, was 45 pounds; the Orphanage is on much higher ground than Dean Peck's establishment. The pressure in the Italian quarter, 36th and Tejon Streets, is less than at St. Vincent's Orphanage.

488 The pressure at the hydrant on the east side of Boulevard F is probably not adequate to fight a fire in Dean Peck's establishment, but protection of that building would not be dependent on that one hydrant. If there were a 12-inch main, there would be plenty of water, even at five pounds pressure.

Hydrant at 38th and Tennyson gave adequate pressure and volume for fire-engine use. At the burning of the Elitch's Gardens building, the engine had all the water it required.

Hydrant at the Florence Crittenden home furnished adequate volume and pressure for fire-engine use; would possibly be adequate without an engine. Hydrant at 36th and Gilpin is all right for fire engine, and pretty fair for use without it.

Hydrant near Clayton College is a long distance from other developed sections. In the opinion of witness, it is inadequate to supply an engine. Clayton School has its own system.

The district in which it is situated is unsettled and the hydrant was on the end of a long single line, which was not gridironed; the

conditions were unusual; the hydrant near the Montclair school was supplied by the booster pump at 29th and Albion. The principal of the Montclair school had made complaint about the pressure, but witness' tests showed that it was all right.

The hydrant at Colorado Boulevard and Colfax showed 105 pounds static pressure and 80 and 25 pounds flow pressure.

Assuming that the main to the hydrant is a 16-inch main, witness thinks trouble must be with the hydrant.

Did not take more pressure tests in business district, because, from experience, witness knew pressure was all right.

Thought that in taking pressures at the depot would yield the highest pressure of any part in the business district; thinks pressure in business district ought to be incerased 35 pounds, but does not need it for engine use; has plenty of pressure and plenty of water with the use of engines. The test on two hydrants at 18th and Wynkoop and 17th and Wynkoop showed 65 pounds static pressure, and no reduction on flow test, indicating plenty of volume.

Have not made more than the two actual gauge tests at those points.

Says Fire Underwriters' Association is an organization of pessimists, which tries to find fault with the way cities conduct their fire departments and water systems, and are usually looking for things to find fault with in both fire department and water system.

Their reports govern the fire insurance premiums; the reports made by the National Fire Underwriters Association in 1905 and 1910 were made after an investigation conducted in Denver.

489 Witness took some of the representatives of the association around to make the tests; they tested flow, volume and pressure, opening a number of hydrants at a time. Thinks the standards of the association are just and their determinations proper, and would be glad to have a report of the association to fall back on in case of criticism of his department, or of the water situation, and witness would feel that if the Fire Underwriters' Association said that the water situation was O. K., and if he had the requisite number of fire houses and the requisite number of engines, that he would have a pretty good record to show to the public in case of criticism.

If the report of that association should endorse the fire department, the witness would think it was a good recommendation; and would have same judgment in respect to the report of that association on the water system.

Since giving direct testimony, witness has thought of a fire at 1913 Clay Street on January 12, 1913. Streams were taken from the hydrants at 21st and Clay and 21st and Decatur, and the pressure was poor; when the engine was put at work at 21st and Clay, the one working at 21st and Decatur had to be discontinued, for lack of water, and it was necessary to put on seven-eighths inch tips. When there was 150 pounds pressure on the engine, the soft suction collapsed, but at 100 pounds pressure the hydrant supplied all the water wanted. Witness thinks the volume at that hydrant was not adequate. Never became thoroughly acquainted with water

pressures, except on Capitol Hill district and parts of north side; always worked in the downtown district.

A great many years ago, when Hendrie & Bolthoff had a fire in the bottoms, the hydrant at Staunton and McNassar Streets was not sufficient to supply an extra first-size Metropolitan engine; at the zinc company fire attachment was made to a hydrant on the old South Denver plant.

At the fire on January 5, 1913, on Clay Street, near Zang's brewery, the hydrant was probably on a dead end; and at the fire at 1218 Clarkson Street, in a two-story flat-roofed house, the adapter was used, and the water just fell out of the garden hose that was attached, but the fire was put out without the aid of an engine. Witness describes other hydrants near 12th and 13th and Clarkson, which he says will not furnish water to put out fires without an engine.

There are many localities where the pressure will carry the water up without an engine. Had to use an engine at 1749 Pearl and at 1576 Pearl.

490 Have never had any trouble with an engine north of Colfax, in the dry district, but not sufficient water there to put fire out without engine; with the additional pressure specified by witness, many fires could be put out without engine; with plenty of chemical engines would have just as efficient means for fighting incipient fires.

Redirect examination by Mr. Stevens:

Witness states that he did not say that with sufficient chemical engines lack of efficiency in pressure would be supplanted; but incipient fires could be put out; any time a fire gets away from the firemen it is necessary to have a big stream.

The city would not be as well protected if the fire department had all the chemical engines which it needs and the present fire pressure was maintained, as it would be if the pressure was increased as detailed by the witness. There is a very small percentage of fires which are known as incipient fires.

If the building takes fire, water is better than chemicals. With a two and a half inch lead of hose on hydrant, and 700 gallons of water passing through it per minute, you have an adequate supply, and no matter how far the fire is, you are going to head it off.

Has never known of pressure of 115 pounds in down-town district.

Has successfully fought fire in down-town district without an engine. Every large fire has to be fought with an engine. Can fight to the third story without an engine, with 65 pounds pressure; 65 pounds is the highest pressure down town. Chemical is used to prevent damage through use of unnecessary amount of water. The nearest engine to the Montclair school is at 16th and Marion, about three miles distant. It would take fifteen or twenty minutes for the engine to reach the school. The fall of pressure

from 100 pounds to 80 pounds at the Mercy hospital indicates small mains.

All fires cannot be fought entirely with chemicals, and witness would desire 75 pounds pressure. When chemicals are used, department should be prepared with a hose line attached to adequate water supply.

Recross-examination by Mr. Dorsey:

Has made no test to ascertain whether there is a pressure of 115 pounds down town. For two years was stationed at City Hall, and pressure was usually 85 and 90 pounds.

491 Redirect examination by Mr. Stevens (resumed):

Witness produced nozzles for inspection.

The second-size fire engine pumps 700 gallons per minute; first size engine pumps 900 gallons per minute, and extra first-size pumps 1000 gallons per minute. Witness reads from Goldsmith's 1910 report, wherein the volume available at certain hydrants is set forth, and quotes from report as follows: "The discharge per hydrant in 12 groups averaged less than 600 gallons per minute, a fair supply for a second-sized fire engine, and 54 hydrants, or 33 per cent of those opened, failed to deliver that amount." (page 12, Goldsmith's 1910 report).

Cross-examination by Mr. Dorsey (continued):

Says no pressures in down-town district exceed 65 pounds. Tested two hydrants which were considered to have as high pressure as any in the down-town district; would not undertake to say that at some time other than the time of test they would not show differently. Knows that the Public Utilities Commission installed recording gauges in various fire houses in the month of June last; witness gave permission therefor.

Gauges were placed on service pipes; only saw the gauge at 18th and Blake, and never paid any attention to it. Never looked at the records; only knows what the pressure was at the points tested by witness at the time of testing.

Takes an engine about 15 or 20 minutes to get a good head of steam after arriving at fire.

Steam pressure should not be less than 100 pounds. Engines maintain about five pounds of steam in quarters. Fire is started as soon as engine goes out of door.

When engine arrives at fire it can furnish fairly efficient service, but it takes ten or fifteen minutes to get maximum service. At first they just allow the pump pressure to run through the pumps.

Witness met Mr. Goldsmith in 1910 and went around the city with him; thinks the data upon which Goldsmith's conclusions are based is correct. Since that time conditions have changed for the better in the fire department. Witness does not know about the change in the water company's system. Knows of a number of

hydrants which would not supply water to a first-size fire engine working under a full head of steam. Does not see why Goldsmith's opinion expressed in 1910 should not be correct.

Goldsmith's criticisms of fire department were probably correct when made, but have been rectified.

Department is larger, engines are in better shape and men are better trained.

492 The nozzle produced in court is the one used on engine work, and is larger than that used in residential sections.

Ordinarily, a first-size engine would not take over six or seven hundred gallons per minute, and to furnish that much from a second-size engine would require it to work to the limit.

These first or extra first-size engines working at 175 or 200 pounds pressure, deliver between six and seven hundred gallons per minute. At large fires they are worked to that extent. The second-size engine will take less.

In the districts around the packing houses and lumber yards the fires are so intense that a hard driving stream is necessary, and the engines are forced. This does not occur at the ordinary fire.

Witness was cross-examined as to the table read from page 11 of Goldsmith's 1910 report. (The testimony is not abstracted because the witness tries to tell what is in the Goldsmith report, and that report speaks for itself.)

At 33rd and Arapahoe a first or extra-first size engine would pump the hydrant dry. Witness assumes that every statement Goldsmith made is correct as of the time made.

Thinks Goldsmith would know whether system of Denver Union Water Company was efficient.

Does not know whether Goldsmith's recommendations if followed would increase the water available at the hydrants.

Redirect examination by Mr. Stevens:

Witness points out location of hydrant on South Logan and Exposition Streets.

Recross-examination by Mr. Dorsey:

Witness was called on to state what was meant by the tables in the Goldsmith report, and was not able to add anything to the statements in the report.

Witness does not know that hydrant reported by Goldsmith to have furnished 1030 gallons per minute was not the one at Exposition Street and South Logan; that hydrant being one of a group that were tested together, and the remainder being on the city's mains.

EBEN PIERCE MASON, a witness for the defendants.

Direct examination by Mr. Stevens:

Master mechanic of the fire department for fifteen years, prior to which time he was assistant engineer and engineer; assisted

3 7 3

Healy in the hydrant tests of which he testified; made no
493 independent observations; took the readings and marked them down; Healy correctly stated the readings.

Cross-examination by Mr. Dorsey:

Began to take the tests the first week in June, continued for three weeks off and on, maybe two days in one week, three days in another; took them every week for three weeks, beginning the first week in June, on various days in each week; cannot give the day on which any particular tests were made.

Does not remember what tests were completed; the last test was taken before the first of July and after the 15th of June.

CHARLES J. MUNZ, a witness for the defendants.

Direct examination by Mr. Stevens:

Resides at 1192 So. Gaylord Street, corner of Arizona and South Gaylord; has lived there eight years and owns the property; four lots, eight rooms, and full basement. During all that time has taken water from the Denver Union Water Company. When he first moved in his house, had difficulty in getting water for irrigation purposes. The district was then sparsely settled. As more houses were built, the service became worse, until it became almost impossible to get water for irrigation purposes during irrigation hours, and finally no water was available at all for irrigation or domestic purposes during irrigation hours.

Describes location of his residence with reference to Exhibit A. In May, 1910, there was no water at all in his district during time the connection with a large conduit built from Marston lake was being made, except a small amount of water that would come into the pipes at night, and that water was filled with rust and sediment.

About six years ago there was a fire in the district, and the hose was attached at Arizona and So. Gaylord, and the water went about six and a half feet from the tip of the hose. Was for a long time president of the South Denver Improvement Association.

Innumerable complaints came in relative to the water pressure; water was inadequate for domestic, irrigation, toilet and bath purposes, and there was absolutely no service; this condition existed up to 1910. In May, 1910, citizens waited on Mr. Robinson, and the pipes supplying witness' district were connected up with 12-inch pipe; this gave 25 pounds pressure. The next year the water supply failed, and the committee visited Marston lake, and found
it practically dry. Witness visited Mr. Hayden, and the
494 company put up a pumping station at the corner of Jewell and South University; put in another pipe and connected it with the 12-inch pipe which was laid in 1910. From that time there has been a sufficient water supply. In the morning, when the pumps are running, the pressure is about 90 pounds, but when the consumers begin to take the water, it falls to about 45 pounds. The pressure is weaker now than it was, because more houses have

been built in the district. At the present time the pressure drops from 60 pounds at six in the morning, to about 25 pounds at 7 A. M. o'clock, when many people are irrigating. Has had no difficulty getting domestic water during irrigation hours since pumps were put in. Reduced pressure has no effect on service, except that it takes longer to irrigate than it did when pumps were first put in.

Witness has always suspected that when the water company put in the 12-inch pipe in 1910 they never opened up the valve to let the water go through it.

MICHAEL FINNERTY, a witness for the defendants.

Direct examination by Mr. Stevens:

Resides at 1417 Gaylord Street; has lived there ten or eleven years, during which time he has taken water from The Denver Union Water Company for domestic purposes; in the summer time, during lawn sprinkling, the water pressure is light; the house is a two-story house, and when water is used through the hose on the lawn, witness gets very little water on the second floor. If the neighbors are using water at the same time, gets scarcely any water at all; sometimes can't get any. In the winter time, when there is no irrigation, the pressure is sufficient. Has no difficulty getting water on the first floor while hose is working on the lawn, but it runs very slowly; might get a little water upstairs.

Cross-examination by Mr. Dorsey:

Lived in the house fourteen years; purchased the house already built; does not know when it was constructed; might have been built more than ten or twelve years when purchased by witness; built by a man named Halley; witness purchased it from a bank up at Fort Collins.

Property includes two and two-thirds lots, second house from the corner; one service pipe; house and lawn-sprinkling come from one supply pipe; never measured the service pipe which has
495 been in the ground ever since house was built; never had any necessity to make a change; has one lawn-sprinkling tap, located on the south side of the house, coming up on the inside of the house and running through the wall; uses a half or seven-eighths inch hose; thinks main to which service pipe is connected runs down Gaylord Street; does not know size of service pipe; it is galvanized iron pipe; 15 rooms in the house, one tap in the kitchen, one in the wash room on first floor, four in bath room and one in a bed room; two water closets, one on second floor and one in basement; never made complaint to water company. Witness seemed to get fully as much water as neighbors, and did not think it would be of use to complain.

Belongs to Water Consumers' League, an organization with the object of getting better pressure, more water, purer water and cheaper water.

Was a witness in the case of The New York Trust Company against the City and County of Denver, and gave testimony with regard to

the Gaylord Street house at that time; has made no effort to correct his situation since that time, except to join the Water Consumers' League.

JOSEPH P. DONLEY, a witness for the defendants.

Direct examination by Mr. Stevens:

Resides at 1920 East 14th Avenue; has resided there five or six years and used water from The Denver Union Water Company; cannot get water in bath room when using the hose; has no trouble in the winter time, but must shut off hose to get water in the bath room on second floor during irrigation season.

Has property at 31st and Julian, North Denver; there is no pressure there; has trees growing there, which he irrigates out of irrigation hours; has replaced two or three since putting them in. In irrigation hours the water runs about four or five feet away from the hose; when irrigating, cannot get any water upstairs.

This condition has existed for six or seven years; this year it has been a little better. Property looks badly. Tenants complain of the water supply.

Cross-examination by Mr. Dorsey:

Did not build the house at 1922 E. 14th St. Got it on a mortgage in 1897. It was built by T. F. Kane in 1893 or 1894. Thinks
the main supplying his house is on the south side of 14th
496 Avenue; does not know the size of his service pipe; thinks it is five-eighths inch pipe and made of lead. Kane built four houses at the same time; one big pipe comes off the main and divides in two on witness' lawn; one service pipe goes to each of two houses; knows that the pipe from the main is big enough to serve both houses; did not see it put in, and has never seen it.

Is merely stating Mr. Kane's opinion that the pipe was large enough for two houses. Only complaint is about supply during irrigation season. Has eight taps in the house, and a laundry in the basement, no barn or garage; two lawn-sprinkling taps, one at each end of the house, coming out from the brick, about a foot from the ground.

Both houses served are nine-room houses. Witness built the house at 31st and Julian about fourteen years ago. Kane made application for the service for that house. Has four lots, and subsequently built four houses there, two of which take water from the water company. The additional house built in 1907. Put in no additional service, but connected to original service pipe for first house. This service pipe is three-quarter inch lead pipe. The additional house has six rooms, with six taps and closets; original house has eight rooms with laundry and six faucets, and one water closet; three-quarter inch pipe runs from service pipe to the new house; has two irrigation taps on each house; trees are located on the parking, and tenants irrigate the lawn.

Witness steals the water for irrigating trees. When running water for irrigation, cannot get water in the bath room. When the

hose is turned off, gets water in both bath rooms; does not belong to the Water Consumers' League; testified in case of New York Trust Company against the city three years ago, and made the same complaint then that he is making now. Talked to Maloney of the water company about it, and he advised bigger service.

J. F. STEADLEY, a witness for the defendants.

Direct examination by Mr. Stevens:

Resides at 642 High Street; been there over five years, owns the premises and has used the water of The Denver Union Water Company. A few years ago complained to the company because he could not get water upstairs during irrigation hours; complained to company and was told that some conduits were about to be connected which would give better service, but service was not improved.

497 Condition still exists, in that during irrigation hours cannot flush toilet. Some years ago had to get water from the basement during irrigation hours, but have not had that trouble this past year, but has had trouble during past year getting water on second floor during irrigation hours; has complained to the water company on account of the quality of water having a stagnant taste; on one occasion was informed that they were flushing out some dead ends; another time company stated that new conduits had been put in and there was a creosote taste in the conduit; the water tasted the same no matter what was stated to be the reason therefor.

The inspector took a sample of this water, but made no report. The house has six rooms, two stories, three lots; two houses built on three lots.

Cross-examination by Mr. Dorsey:

Supervised building of own house.

Thirteen taps in the house and toilet, two sill cocks for the lawn; the main supplying the house is in High Street; does not know the size of the service pipe; pipe is galvanized iron.

(Testimony of witness as to statements of plumber stricken out.)

Water runs in the bath room during irrigation season, but not sufficient for the toilet; service has improved recently, but still has trouble with toilet during irrigation hours; is not a member of the Water Consumers' League, or Citizens Party; testified in the New York Trust Company case three years ago about the same complaint that he is now making.

JAMES N. FLOOD, a witness for the defendants.

Direct examination by Mr. Nye:

Witness is a machinist; has studied steam and electrical engineering, and for eight years has been engaged in the construction and erection of machinery for Hendrie & Bolthoff; has been particularly engaged in selling and designing mine and mill machinery and

the erection and operation thereof. Witness further qualifies by detailing his previous employment.

Has become familiar with all kinds and classes of machinery, mechanical equipment and supplies, and with cost price thereof.

In the fall of 1913, assisted the committee of engineers of the Public Utilities Commission in valuing certain property; was instructed to fix prices as to going prices of today, and did
498 so. Witness prepared the list of property to be valued by him, assisted by Mr. Angel and some employes at the works.

Visited each plant, and starting with power equipments, took all main units, description, capacity, and secured all available information; listed fittings and valves, and stock; prices applied on pumping units were obtained from manufacturer; covered all the property in the several classifications which he was handling, and made inquiry to determine whether his lists were complete.

On some small items applied depreciation; but on larger items submitted to the engineers, did not deduct depreciation, but merely advised the engineers thereof. Witness's original cost figures on Schedules F and I were carried forward by the engineers. Has not examined to see whether his exact figures were used by the engineers, but is certain that they applied approximately the depreciation to items F and I as stated by the witness.

Witness reported depreciation only on items where in his judgment special depreciation should be applied. Each item in Schedule I, stock, was listed and separately priced, and no depreciation was allowed; was assisted by Mr. Angel, and a representative of the water company was present.

(Exhibit No. 19 introduced in evidence.)

Cross-examination by Mr. Dorsey:

Witness took inventory of West Denver storehouse, assisted as stated.

Witness personally listed stuff in the yards. Stock is listed in Schedule I; witness examined Schedule I in Exhibit 19 and states that figures set down under the heading "Net Value" are the determinations made by him with respect to stock at each location mentioned.

Witness thinks total of $111,132.81, being the value of stock on hand in Exhibit 19, Schedule I, is the total reported by him, but cannot say. Assuming them to be such, they are the cost figures based on wholesale selling price f. o. b. Denver. It costs money to deliver the stock to the yards, and arrange and care for and distribute it, and to carry the stock on hand. None of these things were considered by the witness.

Witness undertakes to look at his original figures to see whether such items of costs were included in his totals.

Witness applied the prices which would be quoted by Hendrie & Bolthoff to a concern like The Denver Union Water Company, f. o. b. cars Denver, and company would have to assume costs of

transporting from cars, distributing, arranging, warehousing,
499 supervising, redistributing and carrying the stock. Witness did not consider the item of interest on the investment in the stock.

If Hendrie & Bolthoff take goods from the cars, store them in their own warehouse, and redistribute them, the cost of so doing enters into their price f. o. b. Denver; the item to be added for these costs would depend on class of material. The market price of such material fluctuates.

Witness applied price of $31 per ton to cast iron pipe, which was the price at Denver on the day of valuation, and was the price used by board of engineers on some classes of pipe.

Does not recall adding any overhead charges or interest to his unit prices, but had in mind an addition of 75 cents per ton to allow for unloading cars at the West Denver store yard.

(Further cross-examination reserved.)

Redirect examination by Mr. Nye:

Railroad tracks run into the West Denver yard. There was some second hand pipe in stock which was included in the valuation.

Recross-examination by Mr. Dorsey:

There was considerable used pipe in storage, but upon inspection it appeared to be as good as new and was so listed; it was a relatively small percentage.

Witness FLOOD resumed the stand for further

Cross-examination by Mr. Dorsey:

The figures set down by the board of engineers in Schedule I, Exhibit 19, are substantially the same as those reported by the witness to the engineers. Witness' figures included nothing on account of overhead charge, superintendence, interest on the investment, cost of unloading or cartage, or any charge of that sort. His figures were made up by assigning the cost at wholesale rates on the particular day of valuation for the articles listed, f. o. b. Denver, and no additions thereto were made for any purpose whatsoever.

Witness would add fifty to seventy cents a ton for handling the material; smaller items of stock, outside of pipe, would be handled out of cars to warehouse, handled in the warehouse, and handled out of it; cannot give the addition to f. o. b. cost price in percentages.

Does not feel qualified to express opinion on other items of overhead cost.

Redirect examination by Mr. Nye:

500 Approximately 105 tons of 16-inch pipe, or 15 per cent of the total weight of the pipe, in stock at the West side, had been used.

Recross-examination by Mr. Dorsey:

Total weight of pipe in West Denver stock was 725.62 tons, which was listed at $31 net per ton, or $22,494.22. The fifteen per cent estimate was applied to that figure, and not to the total figures on everything in the West Denver storehouse.

ARMOUR C. ANDERSON, a witness for the defendants.

Direct examination by Mr. Nye:

A member of the Public Utilities Commission of the city and county of Denver since its creation; has lived in Denver thirty-three years, and has been in the real estate business 26 or 27 years. His business included transactions in relation to real estate in the county surrounding Denver. No experience in Douglas county, but has had some transactions in Arapahoe and Jefferson counties, in acreage property; has considered various localities and character of property in the city and county of Denver.

Has had experience in condemnation matters for the city and county of Denver several times. His business has required him to become familiar with all classes of real estate in Denver and vicinity, especially lots and vacant lands, and is familiar with the value of improved and unimproved property in various sections of the city; is familiar with the lands of the water company, listed and scheduled in Exhibit C; has had occasion to specially examine them, and thinks he has been over them personally, in some cases two or three times; in conjunction with Mr. J. I. Carper, working together, witness examined several pieces of land, and where witness and Carper worked together, their valuations were joint and agreed to; work was completed September or October, 1913. There has been little change in value since that time. Does not think there has been any change for the better in the valuation of lands or lots. To arrive at a present-day valuation would make practically no change.

(Defendants' Exhibit 20 was marked for identification.)

Exhibit 20 consists of copies of pages 111 to 115, inclusive, of plaintiff's Exhibit C, covering Class A, lands and rights of way, upon which the value is set down by witness and Mr. Carper.
501 Witness is doubtful about item No. 20, Loretto Heights, which he thinks is the same as item No. 34. The total valuation as shown by Exhibit 20 is $251,207. In valuing item 9, Phebe Strong ranch, the first item of 320 acres was valued without water, the next item was valued with water, and the last item was valued without water.

Item 10, Wm. Strong ranch; item 11, Becky Archer ranch; item 12, Frank Archer ranch, were valued with water. Item 13, Mountain Reservoir Site, valued as acreage, at $5 per *per* acre. Item 16, Marston Lake flume, valued as acreage. Accepted the acreage as stated by the water company. Item 17 was valued in separate parcels, and no value was put on land included in Marston lake reservoir.

Originally, did not value land in the Cheesman reservoir site; outside of that, have valued no land covered by water. Item 18, Littleton mill property, just valued the land as acreage without water. Sullivan reservoir site, valued as dry land, without regard to its occupancy as a reservoir site. Valued item 20, Cherry Creek galleries, as acreage, of more value than dry land on hill. No value as land given to item No. 1, Ashland Avenue reservoir. Ashland Avenue pumping station valued as city lots. De Lappe Place, Cottage Hill and tank site valued as city lots.

Made no determination whether any property valued by him was used or useful in connection with water company's property. Valued land at present valuation in "our judgment." West Denver pumping plant valued as city lots, with reference to surrounding values. Witness used his general knowledge of land values entirely.

Item No. 27, Archer Lake canal and lands, valued as acreage, except where close enough to city to be valued as city lots, and then applied city-lot values; same process as to item 30, Littleton property.

Referring to tailrace, in Exhibit A-4, says it would have larger value for railroad right of way, and is well fitted for that purpose. Land in tract at West Louisiana Avenue is not in built-up section, and acreage value was applied to some of it, and some was given a lot value.

From the Mississippi gallery southward a railroad could acquire right of way over comparatively inexpensive land. Has given no attention to the value of the property for right of way purposes. Witness has given no attention to use of land shown on Exhibit A-4 for railroad right of way, although is familiar with right of way matters. If buying property in question for railroad right of way, would probably pay two or three times the valuation placed on it by witness.

502 (Over objection of plaintiff, witness was permitted to testify as to sufficiency of land on Exhibit A-4 for railroad right of way purposes.)

Says part would be sufficient in width and part would not.

Cross-examination by Mr. Dorsey:

Witness has acquired many vacant lots for himself in the city, but not any lands outside of the city, or farm lands. Has at different times dealt in farm lands or improvements outside of the city for others, in trading, selling or buying.

Has not done much in that line in the last four years; did not deal extensively in lands outside of Denver: bought some lands four or five miles northeast of town, on the river; dealt more largely 20 years ago, principally toward Sand Creek; land was at that time dry land, but now under irrigation; has dealt very little in irrigated lands; dealings have been mostly to the north and northeast of Denver; ten or twelve years ago sold some lands eleven miles south of Denver, on Broadway, a five-acre tract.

Has had other experience, but not much; nearly all of business has been in city real estate; has never dealt in Douglas county, but

some in Jefferson county and some in what is now Arapahoe county; this was 15 or 20 years ago. For the last four years has been on the Public Utilities Commission, and has not done much in buying and selling in the city, but has done a little. Generally speaking, his special knowledge is of lots within the city.

Values in Exhibit 20 represent witness' judgment. Examined each piece of property in company with Mr. Carper, except the Lake Cheesman property, which Mr. Carper did not visit.

Some of the figures on Schedules A and B, Exhibit 19, are familiar to the witness; others are not. Witness turned his figures over to the engineering committee, but witness did not arrange schedules A and B of Exhibit 19.

The valuations on sheet No. 1 of Schedule A, Exhibit 19, items 7-*a* and 7-*b*, appear to correspond with witness' valuation on Lake Cheesman land.

Witness' total value of Lake Cheesman land was $36,299, and the valuation on Schedule A, Exhibit 19, is $35,784, the difference being due to a difference in acreage.

Witness cannot state whether item 2, Exhibit 20, upon which a valuation of $765 is placed, is the intake of the new 60-inch conduit, or is the Strong reservoir site.

Witness does not know whether item 3, Exhibit 20, on which is placed a valuation of $1533, is in Jefferson or Douglas county.

503 In setting down the values on Exhibit 20, witness took them from his former report, and did not recollect exactly what they were. Item 4, Exhibit 20, consisting of 7.768 acres, refers to Platte Canon reservoir site. Witness cannot identify it on Schedule A of Exhibit 19.

Items 5 and 6, on sheet 5, Schedule A, Exhibit 19, are 85.25 and 10.30 acres, respectively; witness only valued 7.768 acres; did not value tract of 85.25 acres because that is the lake; thinks engineers' values exceeded witness' values in some instances.

Did not value item No. 5, Platte Canon filter site, and valued the land only at the Platte Canon power house site, at $700. Item No. 7, Exhibit 20, consisting of parcels No. 5-Jefferson and 6-Douglas, valued together at $1300; all of such value is on parcel 5-Jefferson; no value placed on parcel 6-Douglas.

Did not value item 8, parcel 42-Jefferson, Leehow reservoir.

Witness did not classify Phebe Strong ranch in his list in the same way that it is shown in Exhibit 19. Does not know who distributed the Phebe Strong ranch and classified it under Exhibit 19. Did not value farm improvements or other improvements on any of the land. Witness made some calculations and concludes that engineers' value of Phebe Strong land is the same as his.

Parcel 39-Jefferson, Exhibit 19, value $1600, same as witness' value; the same is true as to parcels 40 and 41, and as to the William Strong ranch, parcel 37-Jefferson, and No. 1-Douglas; nothing has been added to witness' values in Exhibit 20 to make up the engineers' values in Exhibit 19, except some value for improvements.

Witness was furnished a list according to which he made the ap-

praisement. Property was listed by number and parcel. The county numbers and parcel numbers correspond on Exhibit 19 and Exhibit 20.

Visited Cheesman three different times; has never dealt in lands in that vicinity; was offered land near Cheesman for less money than witness' valuation; mountain land, not a reservoir site; did not take into consideration Cheesman's value as a reservoir site; took largely into consideration the amount of money paid by Water Company to the government for it; understood that all land was acquired from the government at $1.25 an acre; made that examination within the last year. Think land was purchased from the government about eight years ago. The fact that the act of Congress granting the land to the water company specified $1.25 was an important
504 consideration, but that was not because the government had valued it at that figure.

Witness did not know that company already owned a great part of the land included in the Congressional Grant; did not know that the land so owned had cost approximately $150,000; understood the government grant was for lands not in the reservoir; originally did not value the land in the reservoir site, but recently valued it at $25 an acre. The board of engineers must have placed their own valuation on Cheesman reservoir in their report to Public Utilities Commission, for at that time witness would not have valued the land in Cheesman reservoir.

Valuation at $25 an acre for land within Cheesman reservoir was discussed with Mr. Fellows, and agreed upon. Witness adopted en gineers' value on Cheesman reservoir lands, and the engineers adopted values witness gave them on a number of pieces. Cheesman reservoir lands may be worth much more. Witness did not value it as a reservoir site. For such purposes, it would be worth more than $25 an acre, as a site. If reservoir is taken away, would not appraise the land at more than $25 an acre; that value is enough for a large tract, without any structure. Land in the site is better land than that surrounding it. It would probably have more value if somebody wanted it as a reservoir site. There are thousands of reservoir sites, but they have no value as such because people do not want them. In witness' judgment, it has greater value than $25 an acre as a reservoir site.

Never knew what the company paid for the land. When a filing has been made on a reservoir site, and some work done, the land has an increased value as a reservoir site.

Has had no experience in buying reservoir sites; never tried to buy one. An available site possesses higher value than ordinary mountain land. Valued the mountain land at $2.50 an acre, and agreed with the Commission on $25 an acre for the reservoir itself; was influenced by the engineers' judgment in giving higher value to land in reservoir site; does not think the land in the site would be worth $25 an acre if it was not a reservoir.

Cheesman lands are in Pike's Peak National Forest; was not aware that the lands could be surrendered and valuable script secured for them; only knowledge of such matters is what he has gained by

inspection of different places through past two or three years, being three or four reservoirs up the South Platte river between Cheesman and Antero.

Has had no definite prices on them; people have said that Commission could get such sites at their own prices; $25 an acre was the engineers' valuation, and he agrees to it; $2.50 an acre
505 for surrounding lands is witness' own judgment; has never dealt in lands in the vicinity; does not actually know whether lands are in National Forest.

Does not know what similar lands in that region have been assessed at, but the fact that such lands had been assessed at a higher value would make no difference with him; does not think the assessor's valuation has any relation to the value at all.

Did not take into consideration any cost that might be incurred in assembling the land.

All the land valued by witness at Cheesman was in patent, and he did not know that the reservoir site was also in patent, or that company acquired a great deal of it by buying mining claims. It would be necessary to buy land before beginning construction, and construction would take several years, during which land would lie idle.

Has not considered loss of interest. There is usually interest allowed for cost and interest during construction, but has allowed none in this valuation. Instead of allowing that, has doubled the value of the land. Thinks a present-day purchaser would have to pay $2.50 per acre. Has considered cost of carrying land during construction. Would allow interest on cost as the plant progressed, and then if the plant was complete, would raise the plant price.

Has allowed double for the land; does not think that interest during construction and expenses of carriage adds to the present value of the land. You are finding what the value is today, and not five or six years ago.

Would not at this time allow interest during construction on the land; would allow it when it was completed and charge it from year to year; has not taken into consideration interest during construction; thinks that he doubled the cost of the land and thereby covered cost of assembling; thinks double the cost of the land to the water company represents its fair value today.

Very little timber in the territory; was offered land between Archer and Cheesman at $2.50 per acre; has not the description of the land offered, and did not see it. Cheesman land covered with small growth of timber. Item No. 2, Exhibit 20, is the intake to 60-inch conduit; this is valued by the witness as dry land at $5 an acre. It is nothing but rocks, some timber, but less than on Cheesman land, but is nearer to Denver than Cheesman lands. Item No. 3, 306 and a fraction acres, valued at $5 an acre; better land than item 2; simply dry land; might be used for pasture, not much grass on it; land located on the right hand side of the river towards the little reservoir above the High Line canal. Was
506 shown the land, and Mr. Skouland was with him at the time. If below High Line ditch, would not be dry land; would be

worth considerably more per acre; has no special familiarity with the difference in value between irrigated and non-irrigated lands in the vicinity; valued parcel in question as dry land. If the land is below the ditch it may be worth $10 or $12 an acre.

Land capable of being irrigated is worth three times as much as land that is not capable of being irrigated. Did not value item No. 4, reservoir site. Figures opposite that item in Exhibit 20 refer to 7,768 acres, not in the reservoir site; justifies this value because part of the land is below the High Line ditch, part above, but around the lake; some could be irrigated from the lake.

Witness' attention was called to the fact that land around the reservoir at Cheesman was valued at $2.50 an acre, and land in the reservoir was valued at $25 an acre, equivalent to multiplying $2.50 by ten, but stated that that multiple was not always to be used as a measure of the difference in value between lands under water and lands around the edge of the water.

Witness thinks that if the water were let out of Cheesman lake, the land under water would be much better than that surrounding the lake.

Witness ARMOUR C. ANDERSON resumed the stand.

Item 9, Exhibit 20, Phebe Strong ranch, valued at $17,930, total acreage 688 acres; 480 acres located on right hand side of road going out are dry land, and valued at $5 an acre; part are good pasture lands and part not very good; are used for that purpose; they are better pasture lands than lands at the intake of the 60-inch conduit. Did not value any land at less than $5 an acre. Valued lands around Cheesman lake, some 7000 acres, at less than $5 an acre.

Land on top of the mountain is less in value. Does not know of any pasture land that can be bought at $5 an acre; is not familiar with the values, sales and so forth in the territory; has not known of any sales, and has had no recent experience in that territory; never has had experience as far as Platte Canon or vicinity of Phebe Strong ranch; got valuation of $5 an acre for pasture land with Mr. Carper, consulting with other people, principally from Mr. Carper. Bases judgment simply on pasture land; don't know what pasture land would cost in vicinity.

Some pasture land is not worth $5 an acre; some of it is worth more; $5 an acre is witness' judgment; would not pay that
507 much for it; was not asking what other people would pay for it; was placing his own value on the land; does not know what people would pay; had no knowledge of how little or how much others would pay; the land formed the basis of his judgment.

The land up at the intake not so good as this pasture land. Some of this 480 acres is excellent land, but is not below the ditch. Is good pasture land; not good for anything but pasture. On 200 acres assigned a value of $15,530, no improvements; included value of adequate supply of water to irrigate the lands; valued the land generally speaking at $140 an acre; some of the land would be better and some land not quite so good; cannot tell exactly how it was

divided; land in good cultivation was valued at $140 an acre, and a less valuation placed on swampy lands near the railroad tracks; that was valued at $50 an acre. Thought irrigated land with adequate water supply that near to Denver would be worth $140 an acre. It is suitable for hay or oats.

If this land had no water on it, it would run from $25 to $30 an acre; can raise some crops on it with no irrigation. The existence of an adequate water supply possibly adds $100 an acre. On looking at parcel 38, Exhibit 19, and the different classes of land, A, B, C and D, it appears that $103 is the highest valuation per acre; did not go as high as $140 an acre, on the Phebe Strong land; went as low as $10 and $15 an acre on some of the 200 acres. What he valued at $10 was dry land, but better than the dry land across the road, which was valued at $5 an acre. The total amount on Exhibit 19 is correct, but cannot say as to the classifications.

Wm. Strong ranch, parcel 37-Jefferson, and No. 1-Douglas, 280 acres valued at $21,074; classification of the land given in Exhibit 19, witness believes to be his classification, as appearing in Sheet 2, of Exhibit 19; very little of the land on Wm. Strong ranch was valued at $5 an acre; irrigated land with adequate water right valued at from $140 to $125 an acre; some not so good valued at $50 or $75 an acre; that would be land with too much water.

Parcels 37-D valued at $15 an acre; that is dry land, below the road and above the ditch. This is better land than the 160 acres in the Phebe Strong ranch that was valued at $5 an acre. This is not under ditch, but crops are being raised on it.

Item No. 11, Becky Archer ranch, 160 acres, valued at $14,120, was not classified; consists of parcels No. 36-Jefferson and No. 1-Douglas. Thinks probably the classification of parcel 36 on Exhibit 19 is witness' own classification.

508 Witness' report in writing to the engineers of the Commission substantially same as Exhibit 19. Valued dry land on Becky Archer ranch at from $10 to $30 an acre; put some dry farming land in at $10 or $15 an acre.

Thinks $125 an acre for irrigated land was the highest value on Becky Archer ranch; that value was put on 100 acres; cannot locate the land that was valued at $140 an acre, but was under the impression that some had been valued that high. There is a question whether these ranches could be called good irrigated land.

Water company's use of the water might interfere with the crops. Valued under the actual conditions; would probably have assigned considerably higher value if the water right had been better. Frank Archer ranch, item 12, valued at $37,490; there is 160 acres of dry land, at $5.00 an acre; 157.6 acres was valued at $4190, or $25 an acre, approximately; may have been all swampy land or low land, does not recollect; has not seen land in a year; 260 acres valued at $125 an acre; thinks the figures for acreages were secured from the water company; thinks Mr. Skouland told him what land had water and what land had not; the land was not classified by the water company—by Mr. Skouland.

All the acres in the Frank Archer place valued as irrigated land were 260 acres, except some that may have been valued at $25 an

acre; witness' classification indicated 260 acres was all the good irrigated land in the Frank Archer place; and on that witness put a value of $125 an acre; valuation on the Mountain reservoir, item No. 13, $5 an acre, valued as pasture land; stream of water running through it; this land might bring $5 an acre, and it might bring more; suitable for mountain ranch. Had no actual sales to guide judgment; did not value No. 14, dam and headgate of the Harriman ditch; did not value item 15, Harriman lake.

Made correction of sheet 3, Exhibit 19, value of Mountain reservoir; Marston lake flume, item 17, valued at $250; valuation about $32 an acre. Don't recall how that value is justified; valued a part only of item No. 17 at Marston lake reservoir; did not value Marston lake, but valued lands outside of the lake in different parcels; parcel 14, Jefferson, 55 acres, $1750, some at $50 and some at $10 an acre.

Has no idea what the lands cost The Denver Union Water Company when purchased; never investigated; had not the same interest in that as he had in the cost of Lake Cheesman land; whether company paid $10 or $100 an acre would make no difference in witness' valuation; the cost of Marston would be immaterial, for the land valued by witness has changed; it is now wet and soggy; conditions have also changed as to Cheesman but witness did not
509 take those into consideration. One parcel of land around Marston lake, containing 16.848 acres, valued at $500. Parcel No. 15, 28.44 acres, valued at $15 an acre; land was low land.

Probably good land before reservoir was built, and then was worth much more; land injured as result of reservoir construction, and valued in its present condition; parcel 20, 67.28 acres, $30 an acre, total $2018; this is seepage land. Does not know cost to the company; less valuable than when reservoir was built. Witness' valuation not for water works purposes; land has no particular value because of being around edge of the lake, differing from land around Platte Canon reservoir. If reservoir was fenced 100 feet from margin, the land would not have an advantage to the lake; does not know what sale price of the land would be; land is not desirable land.

Fixed values without any knowledge of market; merely going out over the land and passing on it. Item No. 18, Littleton mill, 3½ acres, valued at $2500, occupied by the mill building and grocery store; several years ago dealt in Littleton property; dealt on a lot basis; as a matter of fact, land not at the end of the main street; no lots in Littleton selling at the present time. Knows something about it, not very much; does not deal there, and has not for ten years; had a pair of lots at Littleton, and carried them for some time, and sold at a loss.

On a parcel of 10 acres at Littleton, placed value of $1000, river bottom land, not valuable for city lots; picknicking grounds next to it; the three and one-half acre tract could not well be divided into lots; valued at about $750.00 an acre.

Just looked at the land and for reasons satisfactory to witness, made up his mind that it was worth a certain value; does not believe it would sell for that.

Sullivan reservoir, item 19, 80 acres, $12.50 an acre, total value $100; part of it available for dry farming, part is not; nine or ten miles from Denver; no houses on it.

Don't know of any sales in that vicinity in recent years; judgment based on his own opinion. Item 20, Cherry Creek galleries, mostly in bed of the river along the creek, low land, 147 acres, value $4125.

Item of $1000 in ink marked "error", should not be there.

Thinks few people would buy the Sullivan reservoir for any purpose; did not value it for water works purpose.

Witness wrote "Loretto Heights, 20 acres, $1000," on original Exhibit 20; item 34, parcel 15, Exhibit 20, is valued at $500; this is witness' valuation of Loretto Heights, on a basis of 20 acres; thought it contained 40 acres when he put a valuation of $1000 on it. Thinks part of it is used for right of way; even if he is mistaken about right of way, Loretto Heights probably should be valued at $500;
510 rough, rugged land, not very desirable; located a little south of Loretto Heights, very close to the city limits. Never dealt in lands in that vicinity; most land there is under irrigation. This land is under ditch; could be irrigated if it had water.

Has no knowledge of the value of irrigated lands in that vicinity. Witness looked at the land. Does not believe there has been any sale there for quite a while; did not investigate the question. Speaking generally of his land valuations, he did sometimes investigate sales, but not very much; did not value item 21, Ashland Avenue reservoir; the engineers placed valuation on that parcel. Item 22, Ashland Avenue pumping station, valued four lots at $100 each, and seven lots at $75 each, total $925; four lots are valued as a corner and given a higher value. Recently bought four lots on the corner of Vrain and West 29th Avenue, from a quarter to half a mile east of the pumping station, bought the lands from an eastern party; lots item 22, are at Tramway transfer point; this did not influence witness.

Item 29, De Lappe Place, three and one-fifth lots, valued at $450, or $140 a lot; are in front of and across the street from lots valued at $75 a lot. De Lappe Place lots are within the city limits; the other lots are across the city boundary. The lots are curbed, which should be worth $65 a lot.

Lots inside the city are more valuable. Taxes are higher in Denver than in Jefferson county. Item 24, Cottage Hill tank site, 43 lots, $50 a lot.

Has no knowledge of recent dealings in lots there. Real estate values in Denver have had a marked slump in the last year or two. No demand for outside lots. Such condition is not permanent.

Does not know whether present condition is temporary or not. Made the value of the De Lappe lots a year ago, and thinks they are worth as much at the present time; possibly could not get as much as you could a year ago. Market conditions may remain the same for a year or so; believes they will improve; does not know of any buying or selling of lots in Cottage Hill.

Does not know of any recent sales in Cottage Hill. Lots 1 to 33, block 20, Cottage Hill, valued at $50 a lot.

Did not know that within 60 days lot 33 had sold at $175; did not know that lots 8, 9 and 10, in block 22, Cottage Hill, had within 60 days sold for $175 a lot; that fact would not affect witness' judgment, unless he knew something about the causes of the sale; if it was an ordinanry sale of real estate, witness would not be influenced by it. Does not think the lots are worth the money. Witness fixes his judgment independently of what other people say or are willing to pay: Item No. 25, appearing on Exhibit A-4, parcel No.
511 14, three lots, valued at $300 a lot, total $900. Has never dealt in lots there; does not know of other people dealing in them. There is nothing the matter with the lots; they are less than average size; had no knowledge of what lots were selling for in that locality; just looked at the lots and put a value on them; did not know that such lots had been selling at seven or eight hundred dollars a lot.

Was trying to ascertain what the lots were worth; represents witness' judgment without regard to sales made; knew nothing about sales made.

Valued 9¼ acres at $3000; has not dealt in property in that vicinity recently; does not think any property was selling around there; took his own knowledge as far as able; does not know that property in that vicinity had recently sold for from seven to eight thousand dollars an acre.

Parcel 15, one acre, valued at $3000, and 20/100ths of an acre, valued at $750; simply went out and looked at the land and put down its value, without knowing anything about sales. Item No. 26, tailrace, valued at $6210, one and nine-tenths acres being valued at $1500 an acre.

Valued a part of tailrace at $900 an acre. Knows nothing about sales there. Adjoins Baker's Villa. Some lots in Baker's Addition and Baker's Villa sell at $250 a lot, and some do not.

Tail race is lot land; it is a narrow strip of ground and down in a gulch or ditch.

Witness deducted from the value of this parcel because it is used for running ditch. Item 27, divided into a number of parcels, valued at $53,076.

Some of the parcels valued at $100, some at $150, and on up to $3000 an acre, without any consideration of rights of way. It would be worth several times that value for right of way; might cost more for a ditch right of way than for a railroad right of way; left all such matters out of consideration, and valued it simply as lots and lands; placed a higher value on lots near town; mile or two from the high-valuation territory placed lot values.

Parcel 17, 3.3 acres, valued at $1500 an acre; parcel 18, $1500 an acre; don't think any property has been selling out there; doesn't know that water company paid for one acre, constituting parcel 18, $3000; did not investigate. That price might have been paid for special reason; does not know that adjoining ground is held at $3,000 an acre.

Was told by Mr. Bartels, of Bartels and Blood, that the owners had no valuation on it. Witness could not get any valuation, so put his own on, at $1500. Parcel No. 18, 88/100ths of an acre,

valued at $1320, or $1500 an acre; about one block from the D. & R. G. shops; deducted from its value because it is a narrow
512 strip. If it had been a large tract of ground, would have placed a higher valuation on it.

Did not know that the D. & R. G. was expanding its shops in the direction of parcel 19.

Parcel 20 adjoins parcel 19, and is valued at $750 an acre, parcel 19 being given a higher value because nearer town; does not know the values of the lands held on either side.

Does not know what Middaugh holds the adjoining land for; did not inquire from Middaugh or from the Rio Grande railroad; does not remember making any inquiries from anyone. Parcel No. 22, 1.127 acres, valued at $750; does not know that the company paid Middaugh at the rate of $5000 an acre for adjoining property.

Witness deducts from value because of the shape of the piece.

Knows nothing of sales in that vicinity. Parcel 23, valued at $600, irregular shaped; low value because of the shape of the parcel; parcel 21, valued at $750, for the same reason; item 24, valued at $600 an acre, total $12,600, or about $90 a lot after taking out streets and alleys; land lies low; immediately adjoins Bailey's Addition; knows nothing about the market value of lots in Bailey's addition. Parcel is right in the lake; don't think there have been any sales in Bailey's Addition.

Don't know what the owner of Bailey's Addition is holding lots at. Parcel 24, 10.20 acres, valued at $2250, or $225 per acre. Parcel 26, 8.34 acres, valued at $2500, $300 an acre; Adjoins Richthofen's Addition; does not know of sales in Richthofen's addition at $150 a lot; any such bona fide sales would affect witness' judgment.

Twenty-lot sale would be a small purchase; such a sale, if bona fide, would indicate a value of approximately $1500 an acre. Parcel 27, 5.184 acres, about $300 an acre, total $1500.

Don't know of sales in Norwood's Addition. If somebody bought 20 lots to put building on, it might not indicate value.

Does not know the values allowed by the Alameda subway condemnation commission. Witness' judgment would not be influenced by consideration of fact that condemnation commission allowed $200 per lot.

Witness has served on condemnation commissions and allowed more than land was worth.

Parcel No. 28, 7.896 acres, valued at $1200, or less than $200 an acre. Placed lower value because of shape of the ground. Considered parcel by itself without regard to ownership of adjoining ground. Item 30, 15.847 acres, total value $2250, approximately $150 an acre. Made no inquiry to ascertain the value of adjoining ground; did not know that in 1912 a tract adjoining parcel 30 was sold at the rate of $2000 an acre.

513 Parcel No. 31 containing 20 acres valued at $6000, as acreage.

Don't know whether the parcel would be good for truck-gardening; knows of no adjacent truck gardening ground being sold for $1000 an acre. Parcel 32, 6.06 acres, valued at $900, $150 an acre.

Thinks narow strip like this parcel could not be sold for more

than $150 an acre; land is river bed gravel land; does not know that gravel pits are being operated right near it; knows nothing of the value of gravel pits.

Never heard of gravel lands being sold for $1000 an acre. Parcel No. 33, 13.31 acres, $100 an acre, $1331. This comprises the Mississippi Street galleries; simply valued it as land; did not inquire about circumstances connected with company's acquisition; does not know that the company paid $12,000 for the land; did not attempt to ascertain what it cost or was sold for years ago; did not consider its value for gravel.

Did not find how many acres in the parcel were inside the river and how many acres outside, or how much was available for gravel-bed purposes.

Parcel 34, about a quarter of an acre, valued at the rate of $300 an acre; adjoins parcel 33; would be on Louisiana Ave. if the street were opened through; being 400 feet long, would have more value than a square tract; it is 30 or 40 feet in width; controls the other land, and would be an outlet to the street if Louisiana Avenue was opened; is not sure but what the land would be 40 or 50 feet away from Louisiana Avenue. Parcel 33, opens on Mississippi Street, which is the main thoroughfare through that part of town, a bridge being across the river at that point, but added nothing to parcel 33 on that account; land runs down to Florida Street, near Overland Park; does not know what Overland Park was recently sold for.

Total value on item 27, $53,076. Item 26, $6210; item 25, $32,400, aggregate of the items $91,776.

Witness does not say that he could buy and assemble property shown on Exhibit A-4 in the same or adjacent locations for $91,776. Thinks it would cost two or three times that, or probably more. Does not think that the cost of duplicating would be any measure *or* value. Bought some lands recently for the Burlington railroad, where they paid four times its value. Item 28, four lots in University Park, $50 a lot.

Item 30, office and superintendent's residence, Littleton, $2800, does not include improvements; storage tank, Highland Park, $500; item 32, lots in Cottage Hill, 46 lots, $2025, less than $50 a lot; not so well located as other Cottage Hill lots that were valued.

514 Does not know about the recent sales in Cottage Hill.

Item 33, valued at $240; item 34, more or less a right of way, and no value placed upon it; that was valued by engineering committee.

Item 35 not valued; item 36 not valued; the 20 acres at Loretto Heights are a part of the right of way.

Did not value item 37, right of way constituting easement only; must have been valued by engineers' committee; did value some rights of way, but has no figures; remembers valuing some rights of way, but they are not included in Exhibit 20; has added nothing on account of overhead expenses. Bought land for the Burlington railroad for railroad right of way; most of it had some improvements on; the railroad had a number of agents at work; witness received compensation from those from whom the land was bought, the usual percentage. The prices paid in some instances were two or three times actual value.

Took a year or more to secure the right of way. About two years from the time first money was invested until the track was put in operation; the line was laid out before right of way was bought, and all added to the cost.

The cost of land was held inactive for a year or two; this is an element of cost. Such an element was not added in witness' valuation of water company lands.

All the water company lands valued by witness are now assembled and part of the operating property. Value of property is not affected by what it would cost to get it. Did not consider that factor in valuing water company land.

Land values are now abnormally low; did not give that fact any consideration in putting value on items 25, 26 and 27. Did not consider presence of railroad lines in vicinity; did not consider them available for trackage. Has been member of Commission since 1910.

Section 264-*a* provided that city should offer $7,000,000 for property which had been appraised in 1909 at $14,400,000, and that if the offer was rejected the city should proceed to build its own plant.

Has not made public announcement of what the property was worth. The Commission made an investigation in 1910 by Mr. Phillips and Mr. Fellows. Mr. Phillips made a report in writing, which was made public.

(Objection to offer of Mr. Phillips' report sustained.)

Witness did not make announcements to the public as to value of property. There was a bond election on the subject of issuing $8,000,000 in September, 1910; the commission got out a report
August 20, 1910, signed by witness as president of the com-
515 mission, published in printed form; anybody could get a copy; commission made a report on December 31, 1910, for year ending that date, was signed by witness, printed and put in circulation.

(Plaintiff read from that report in regard to valuation of Marston lake, which was ruled out on objection.)

(Plaintiff read from report of Commission on valuation of physical plant, which was ruled out by master.)

(Plaintiff read from report of August 20, 1910, in regard to constructing new plant, which was ruled out by master.)

Witness voted for the appointment of the engineers' committee, who made report in January, 1914, reporting values such as set forth in Exhibit 19; total value reported, excluding water rights and going-concern value, something in excess of $10,000,000; witness has refused to approve the report.

January, 1914, voted not to approve the report, because valuation was too high on some items.

Redirect examination by Mr. Nye:

Witness paid $100 a lot for four lots on 29th and Vrain; witness employed following method in valuing property: After going over the property and looking it over, he placed what, to his mind, was the present, active value of the property at the time he made the valuation.

[redacted]

GEORGE WALTER BROWN, a witness for the defendants.

Direct examination by Mr. Nye:

Lives at 2730 Vallejo Street; has lived in Denver for 42 years; contractor, does work for insurance people, estimating, settling losses; is not regularly employed; has done that work for about 40 years.

Experience has covered valuation of average buildings in Denver and throughout the state; familiar with all classes of building construction; in 1913 made an estimate of buildings, bridges and fences, and some underground work belonging to The Denver Union Water Company for the engineers' committee. Exhibit 19, Schedule H, buildings, made up figures reported by witness to the committee.

Figures represent cost to replace, from contractor's standpoint; second column shows appropriate depreciation; did not make the figures in column 3, but had corresponding figures on his report; made the figures in column 4; net value was determined by witness, and shows in column 4. Visited the different properties and made a complete investigation.

516 Commenced in August and finished in December, or January, 1913. Valuations are as of October 31, 1913.

Cross-examination by Mr. Dorsey:

Did not value farm buildings; valued filter plant and houses used in connection with it.

Valued only strictly water works improvements, except at Littleton, where valued the mill.

Total replacement value on Schedule H, $410,617.24. Did not know that Metcalfe and Anderson's figures, shown on Exhibit A-22 were $451,520. Was not aware that after allowing depreciation witness' valuation was $338,100.03 as against Metcalf and Anderson's $335,519.

WILLIAM F. ALLEN, a witness for the defendants.

Direct examination by Mr. Nye:

Resides in Denver; has been an engineer and contractor since 1894; contracts water works in particular; was employed by the Public Utilities Commission in the fall of 1913, to make values on Schedule D, infiltration galleries, Mississippi Street, Cherry Creek, mouth of Platte Canon; Schedule E, including conduits, directed particularly to the replacement value of the various conduits.

Arrived at cost value for replacement without determination for depreciation, which appears on Schedules D and E, Exhibit 19; Exhibits 21 and 22 were prepared by witness, and show replacement cost of items, Schedules D and E, as of October 31, 1913.

Made no allowance for depreciation. Was actually engaged in the construction of a number of the items valued, particularly the conduits; this gave witness general knowledge of work. Witness thinks his valuation is fair.

Would be glad to replace the property listed on Schedules D and

E, Exhibit 19, at the prices estimated in Exhibits 21 and 22, with the correction of $27,450 on Exhibit 22. Was consulted as to the life of the pipe lines.

Witness furnished the engineers of the commission with judgment as to life of pipe line.

(Exhibits 19, 20, 21 and 22 offered in evidence.)

Cross-examination by Mr. Dorsey:

Has constructed plants at Trinidad, Walsenburg, both sides of Pueblo, Colorado Springs, Leadville, Loveland, Fort Collins,
517 some of the work at Denver, irrigation plants, original gravity system of the city of Seattle, plant for Cambria Steel Company, Johnstown, Pennsylvania; Atlantic City, New Jersey; water system of Colorado Fuel and Iron Company at Pueblo; power plants at Butte, British Columbia; Trenton Chasm, New York.

Member of firm of Holme and Allen Construction Company and C. P. Allen General Contracting Company, formerly C. P. Allen and Son; now constructing Colfax-Larimer viaduct, with C. S. Lambie; C. P. Allen is not now associated, but has been for many years; he used to be connected with The Denver Union Water Company. C. P. Allen was in charge of work for water company when witness was on the work. Schedule D, Exhibit 19, relates to infiltration galleries; figures on that exhibit are not the witness' figures.

Exhibit 21 shows merely the cost of labor and material as to the infiltration galleries; total $102,921.56. Mr. C. P. Allen was engineer of the water company when Mississippi Street galleries, Platte Canon galleries, original Cherry Creek galleries were constructed. The column on the left, in Schedule D, Exhibit 19, states so-called replacement value on each one of those galleries, aggregate being $129,480.78; contractor's profit and interest during construction must be added to witness' figures; total of $129,480.78 may not include engineering and contingencies, but does include contractor's profit and interest during construction. All these elements were ignored in estimates on Exhibit 21. The figure at which witness would construct work in Schedule D, Exhibit 19, is the $129,480.78. Did not fix depreciation allowance, but gave his judgment. The committee of engineers actually inspected the work; does not know how the net value of $102,376.24 compares with Metcalfe and Anderson's net, in Exhibit A-22 of $93,286.

Used present-day quotations on materials; such quotations fluctuate. Judgment as to life of wood-stave conduits based upon witness' general experience.

Engineers for Utilities Commission sough information as to depreciation, estimated future life, and so forth, from all sources, actually inspected the property and had the pipes dug up in many places. Engineers gave conduits ten years longer line than the witness claimed for them. C. P. Allen disagreed with the witness, and some of the balance of the board disagreed with Mr. C. P. Allen. Witness knows that some of the wood-stave conduits are more than 20 or 23 years old, and are still in service; part of one conduit has been in for over thirty years.

Witness estimates thirty years as the total useful life of wood-stave conduits; would apply that estimate to some of the con-
518 duits of the water company. Thinks that some of the older conduits are today in better condition than the new ones: depends upon the construction and design. His observations apply to certain points on the line. This would not materially affect life of whole line, if the fault existing at a particular point were corrected. At present 30 years is the limit of experience with wood-stave conduits. Witness has examined the conduit constructed in 1874, and it was in good condition in 1898.

Would not say that a conduit of the water company that had been in use for thirty years would have no further useful life. There is no question of doubt as to a 30-year useful life, and might be very much longer. Comparing Conduit No. 7, Exhibit 19, Schedule E, gross replacement value of $236,153.49, with witness' figure of $191,-411.14, in Exhibit 22, witness thinks that contractor's profit and interest during construction has been added, possibly overhead charges; this is true as to all figures at the right, in Schedule E, Exhibit 19, as compared with figures on Exhibit 22. Arrives at the cost of conduit No. 7 by considering material, labor necessary for the excavation, backfilling of trench and construction of the pipe, and erection of the various parts.

Witness allows Mr. Metcalfe to use his detailed figures on both conduits 7 and 8.

WILLIAM F. ALLEN resumed the stand for further

Cross-examination by Mr. Dorsey:

Referring to Exhibit 22 and conduits Nos. 7 and 8 and No. 8 extension, listed thereon, it appears that witness' gross reproduction costs, as shown thereon, are less than the estimate of the Utilities engineers for the same item, shown on Exhibit 19; that difference shows contractor's profit and overhead. Witness' estimates on these items do not cover contractor's profit, overhead or interest during construction. The net correction of $27,450.22 appearing on the bottom of Exhibit 22 does not apply to any particular conduit; there is a small amount of it applies to conduit No. 8, but none of it applies to conduit No. 7 or No. 8 extension: $2490.75 is the correction on No. 8, covering some trestles near the mouth of the canon, earth work, loose rock, sacks, culverts, and that amount should be added to the total of $171,011.06 appearing on Exhibit 22 as the reproduction cost of conduit No. 8.

There is a credit of $35 which should be deducted, making the net addition to conduit No. 8, $2455.

519 In estimating conduit No. 8, grouped it into specials, stand-pipes, steel wells, valves, air valves, dam, intake, tunnels, sand-trap, retaining walls, concrete, excavation and trenching. This estimate does not include the plate girder bridge across the river, steel trestles carrying the conduit, boiler house, heating plant at the dam, and one truss span across the river; did not include keeper's cottages at the intake, or telephone system. Did consider the con-

crete covering between the intake and sand-trap; did not include in estimate for the work of excavation at the east portal, because the Rio Grande railroad originally started the tunnel and took out the east portal; one of the predecessor companies of the water company took possession of the old D. & R. G. right of way, on which there was a partially-constructed tunnel, and made use of that tunnel and extended it through for the pipe. There was about 30 or 40 feet of work at the east portal, and the west portal was also started. The Mountain Water Works Construction Company completed the tunnel for the use of what was known as conduit No. 2, and in the construction of conduit No. 8 the water company did not have to build the tunnel. The 66-foot tunnel was constructed in connection with conduit No. 8; the small footage of railroad work had to be enlarged.

The Citizens Water Company employed the Mountain Water Works Construction Company to build the old tunnel, and the Denver Union Water Company acquired it from The Citizens Water Company.

If the D. & R. G. had constructed the entire tunnel and presented it to the Citizens Water Company, witness would eliminate it from his estimate.

Conduits Nos. 1 and 2 were not constructed by The Denver Union Water Company; thinks No. 3 is the first one constructed by it.

The D. & R. G. built a part of the railroad grade up through the canon, and the upper end of old conduit No. 2, which was torn out to give way to conduit No. 8, was laid along the original roadbed. The original work by the railroad has never been estimated in connection with the cost of the construction of those conduits. In order to use that grade for the conduits, it was necessary to enlarge it and deepen the cuts; does not think the original railroad work should be included in the excavation cost; does not know whether the water company when it acquired the railroad grade paid anything on account of the work that had been done. The value of that work would probably be taken care of in the land values.

At the time of making estimates, did not consider the railroad work on the grade. If that railroad work were estimated, it
520 might increase the estimate on the east portal of the tunnel by $2500; that allowance would be based on the water company's estimate of quantity, and witness' unit price of $1.00 a yard. Witness' unit prices were: dry rock work, $1 a yard; for wet work, $2 a yard; loose rock, 75 cents, $1.50 for wet work; earth excavation, 50 cents for dry work and $1.00 for wet work; figured 50 cents a yard for backfilling earth work; does not use rock for backfilling; when the trench is through rock, earth has to be conveyed to it for backfilling; 50 cents per cubic yard is the allowance for putting the earth in and tamping it; has not separated the total quantities on each class of work; has not compared his quantities with those shown by Metcalf and Anderson in Exhibit C on conduit 8.

Witness repeats estimates of unit prices for different classes of excavation on conduit No. 8, to-wit: earth excavation, 50 cents per cubic yard; loose rock, 75 cents per cubic yard; solid rock, $1.00

per cubic yard, which unit prices are doubled where the respective classes must be excavated in wet condition. A small amount of excavation in connection with some cast iron pipe was not allowed on the yardage basis, but witness figured 144 feet of trench at 25 cents per lineal foot; that is exclusive of the trench estimates. On standpipe witness allowed 37 cubic yards of earth at 40 cents a yard, 90 yards of loose rock at 40 cents a yard, 40 yards of solid rock at $1.00; on the conduit proper estimated 14,770 yards of earth at 50 cents, 7950 yards of loose rock at 75 cents, 14,300 yards of rock at $1.00; the work on the trench proper was all dry work; this makes a total of 37,020 yards of dry work.

In consulting the detailed figures, finds that there was allowed 30 cents a yard for excavation; that there would be 11,800 feet of backfilling, on which there was an estimate of 25 cents per lineal foot; applied 20 cents a yard on 14,770 yards of earth excavated, which amounted to the same as 11,800 feet of backfilling at 25 cents a foot; therefore applied a price of 50 cents per yard on the total earth excavation, which covered excavation and backfilling, giving a total cost of $27,647.50 for excavation and backfilling on conduit No. 8. The length of the trench in lineal feet would be 11,800, the total length of the conduit is 12,422 feet, but there is 600 feet of wood stave pipe on steel trestle work requiring no backfilling or trenching; yardage on this trench averaged approximately 3.14 cubic yards per lineal foot, or a total of 37,020 yards. Allowed for backfilling 14,770 cubic yards. It figures the same whether figured at 25 cents per foot on 11,800 linear feet or at 20 cents per yard on 14,770 yards. Didn't know that there was actually 22,202 cubic yards of earth backfilled into No. 8 trench. Witness figured the back-
521 fill and arrived at 14,770 cubic yards. Figures a cover of two feet over the pipe. Figured the trench 7 feet on the bottom and 1¼ to 1 slope on the sides; cubical contents of the trench would be 3.14 cubic yards per lineal foot; the pipe would occupy one yard. After the pipe is placed in the trench, with two-foot cover over it, it would required a yard and a half per lineal foot to backfill the trench; calculates 1.4 yard of backfilling per lineal foot, making 16,500 yards; takes the cross-section of the trench to be 7 feet on the bottom, 7 feet deep, 1¼ to 1 slope.

Witness figures in detail the area of cross-section and yardage per lineal foot, and concludes that there would be 1.7 cubic yards per lineal foot for a level section; the slope of the hill in this case would not increase the backfill. On a basis of 1.7 cubic yards of backfill per lineal foot, the total backfill for the trench would be 20,000 yards. Witness has something like 17,000 yards in his estimate, instead of 14,770. Figured the cost of the backfill at 25 cents per lineal foot, and merely stated that that would be equal to 14,770 yards at 20 cents a yard, so that witness' estimate amounts to 14.7 cents per cubic yard for backfill and tamping; witness thinks that a fair figure, considering that 1428 feet of the pipe would be backfilled by scrapers, at 5 cents a yard. Backfilling would have to be tamped to the center of the pipe, and one-third of the material would have to be tamped by hand; this would cost 2 cents per lineal foot

of trench. The material underneath and around the pipe does not need to be replaced by hand. Conduit No. 7 extends from the end of the 60-inch conduit down to Marston Lake, comprises 52,531 feet of 48-inch wood stave pipe and 333.8 feet of 42-inch cast iron pipe, making a total length of 52,864.8 feet.

Did not include in estimate superstructure over the 48-inch hydraulic valve at the upper end, and the superstructure on the tower at Marston, or the Venturi meter; has no classification for excavation and backfilling on this conduit. Estimated 10,000 feet of trench at 47 cents per lineal foot and 42,685 feet at 43 cents per lineal foot; used a cross-section of 5½ feet on the bottom, 9 feet on top and 7 feet in depth. On 10,000 feet applied 20 cents a yard for excavation and 5 cents a yard for backfilling, and on 42,685 feet applied 18 cents for excavation and 5 cents for backfilling. On the 10,000 feet there would be some gravel work on the upper end of the line, consequently a higher price. Applied those unit prices simply on the total amount taken out. Compares the unit prices on 60-inch conduit of 30 cents for excavation and 20 cents for backfilling, with the unit prices of 25 and 23 cents, respectively, on conduit No. 7.

522 On the 60-inch conduit there were 7,000 feet of work which was hand work and 4800 feet of team work; on No. 7 the entire line was team work and worth less money. Conduit No. 7 was recently constructed by the water company, but does not know its cost in excavation and backfilling; has understood that exclusive of contractor's profit it exceeded witness' estimate. Witness' total cost for excavation and backfilling of conduit No. 7 was $23,054.55. Considered extra work necessary at ditch and creek crossings, but estimate covers that; made no separate estimate of the extra cost.

There is possibly 19,000 feet of conduit 7 in the public road; thinks allowance of 5 cents per yard for backfilling is sufficient to restore the road and clean up the line in nice shape. The tearing down and replacing of fences was considered; concrete and buttresses were separate items, yokes and tie rods were separately allowed; cleaning up the line comes under the general estimate. Has not assumed use of trenching machines; does not consider them practical for that size trench. The contractor on conduit 6 used trencher and lost money. Witness would not attempt to use trenching machines. For small narrow ditch it pays to use a trenching machine when you get below six or seven feet in depth. Has kept accounts on trenching machines as against his own work for pipe trenches where the depth was not over six or seven feet, and found it much cheaper to plow and throw out with shovels. A machine might be a benefit in case labor was short; machine would replace 300 men. Obstructions in the ground make it impossible to use trenching machines; in some parts of the streets of Denver trenching machine could be used. In 1910 could have used a trenching machine on the outskirts of the city; has never thought it would be feasible to use machine except on the outskirts of the city.

Witness made his estimate at the request of the engineers of the utilities commission at a meeting with them the last part of Novem-

ber, 1913; was being continually pressed and hurried. In latter part of November, 1913, had finished estimate on conduits 1, 2, 3 and 4; at that meeting Judge Van Cise urged witness to hurry. Witness was asked what Judge Van Cise said. (Question objected to. Discussion by counsel. Objection overruled.) Had been working on a per diem basis, and wrote a letter to the board stating that the work would be completed by January 1, 1914, but that it might be impossible to do so, and that if more time than that was required, there would be no further charge.

Judge Van Cise said to work up to within four or five days of the first of the year and guess at the balance, and witness refused to do so. Witness took his time and occupied two weeks more than was estimated.

523 Redirect examination by Mr. Nye:

Witness' work was not guess work; it was begun about the middle of September and finished about the middle of January.

In the case of conduit 7, which is constructed along the highway, it would be more convenient to get at the work, and it would be easier to work; it would not be more expensive. As to conduit No. 8, included the equalizing tank near the mouth of the tunnel; excluded the superstructures.

Witness explains the correction of his testimony as to unit cost of trenching and backfilling on conduit 8. Witness bid on the construction of conduits 7 and 8 and offered to do the work on No. 7 for about 30,000 less than the price at which it was let, so had previously estimated the construction of conduit 7, less cost of material. At that time had specifications before him; also had specifications of conduit No. 6 before him; did not bid on that conduit. Tried to sub-contract some of the work on conduit No. 8. (Witness' testimony that his bid would not be considered by the company was stricken out on objection.)

Witness' bid on conduit No. 7 was not accepted. Present estimates on various conduits include necessary work, material excavation and backfilling; profit and other additions were applied by the board of engineers. Trenching machines are variously designed with a view to use upon different classes or grades of work. Was instructed to be extremely careful and fair in his estimate.

J. I. CARPER, a witness for the defendants.

Direct examination by Mr. Nye:

Real estate business and ranching; resided in Denver a little over six years; has done more in farm lands than anything else during that time, particularly around Denver.

Some business in city lands. Assisted Armour Anderson in valuing land of Denver Union Water Company in 1913. Had a list of property and plat, went over the property, looked at it and valued it at what, in witness' judgment, it should be. Possibly some of the investigation was comparing prices of lands which had been sold

in vicinity, but opinion chiefly based upon what, in own judgment, was the real market value of each separate tract, tested by experience and what the value would be to party who desired to buy each particular tract—not what it would bring if placed on the market, particularly.

Applied all information obtainable to individual experience and judgment in arriving at value. Lands valued in October and
524 November, 1913; there has been no fluctuation since that time. Has checked in detail values set down on Exhibit 20, and are correct.

Did not assist in valuation of Lake Cheesman, but concurred in all other items on Exhibit 20. On printed page 113 of Exhibit 20 there is "Loretto Heights, 20 acres" and on page 15, item No. 34, parcel 15-Arapahoe, No. 28, contains 20 acres; there were not two parcels of 20 acres, each; has identified said parcel 15 as Loretto Heights; total valuation given on exhibit is correct. Did not value lands covered by reservoirs; valued lands surrounding reservoirs; visited the Strong and Archer ranches; valued some as lands with water and some without. Information was that water rights were good, priorities early, but that every year some water was taken for the city, and all subject to the city's needs.

(Exhibit 20, with the exception of item 1, offered as Mr. Carper's detailed testimony.)

Cross-examination by Mr. Dorsey:

Office in the First National Bank Bldg.; does business as the Denver-Colorado Securities Company, Holland Farm Company, Denver Surburban Farms Company, Altura Suburban Farms Company, has associates in these companies and is an officer therein; they deal in lands on their own account; dealings in city lands carried on through such companies; have bought some city lots and sold them and built on a few; principal business has been in outlying land.

Thinks $35,000 or $40,000 in six years would cover city real estate dealings; is not a real estate broker; has handled his own business; city property dealt in has been in Capitol Hill and Park Hill; never saw Lake Cheesman. Item 2 is mountainous and rocky, not available for agriculture, nor good grazing land; $5 an acre. Item No. 3, Exhibit 20, 306.65 acres, somewhat rolling and rocky, better than land in item 2. $5 an acre is value of item 3, and used that as minimum, so did not value item 2 at less. High Line ditch is above item 3.

Land could be irrigated, but is not; is too rough. $5 good value for grazing land in any place situated as item 3; not familiar with sale prices in that vicinity; would be glad to sell such land at $5 an acre; has dealt in grazing land east of Denver, near Greeley, and in southeastern Wyoming; land east of Denver was located about eight to ten miles from the city limits; purchased that land in 1909; have disposed of all of it; did not sell as low as $5 an acre; bought from A. D. Wall; thinks price was $5 an acre, but witness

sold it at $10 an acre; does not know whether item 3 is part
525 of the sedimentation basin; appraised seven acres and a fraction in item 4; land is dry and rolling, above the reservoir; some portion of it was good, better than item 3; valued that at between $12 and $15 an acre; land may be under the High Line ditch; thinks that is good value without water being on it.

Took into consideration the fact that the year 1913 was a year of great inactivity in real estate. It is a fact that one selling now would have to take less than normal rates, and tried to keep that in mind. Witness thinks lands would be worth more at normal times; considers that the tract is a small tract, and also the way of approach to it. Parcel 4 immediately adjoins parcel 5, where the lake is. If the lake was not there, there would be a tract of 90 acres. If the land was in one body and the lake was level, like portions of the 7 acres, and the approach was normal, would value it higher.

Irrigable land under the High Line which has no water right might be worth $12.50 to $25 an acre. Parcel 4 is small acreage tract, and took that into consideration. Did not value item 5. Part of item 6 is like item 6; this is the place where the power house and cottages are located at Platte Canon; valued that land at $30 an acre, as dry land under a ditch, without water rights. Tried to give all land fair value. Item 7 valued at $65 an acre; does not recall how that varied from item 6; did not value item 8.

Made a different classification of Phebe Strong ranch than that given under item 9. Valued 320 acres at $5 an acre, fair grazing land; thinks could buy grazing land in that locality at that price; never tried it, but can buy grazing land close to Denver, just as good, at that price, lying in immediate connection with irrigated land; cannot tell where to get such lands right near Denver, but can up at Greeley; has no knowledge on this subject with respect to grazing lands in the vicinity of Denver; knows of no sales in the immediate neighborhood of any lands exhibited on Exhibit 20. Don't recall whether endeavored to ascertain evidences of sales in the vicinity of lands valued. Phebe Strong ranch, according to witness' notes, priced 103 acres at $125, 67 acres at $15, 15 acres at $10, 15 acres at $100, classified because of difference in lands and water rights; maximum price was $125; land is excellent; would be worth more with an adequate water right.

Can get such lands with adequate water rights in normal times at $125 an acre. Bought a lot around Denver and Greeley at less prices than that. The best crop that can be raised on these lands is alfalfa; cannot pay more than that for alfalfa land; the nature of the water right limits the kind of crop, but value of $125 an acre does not represent witness' judgment as to value of land with adequate water right.

526 The water right must itself be good with reference to the date of the filing, but the water being subject to withdrawal, the land and water was figured at $125. An assured water right would add to it. The highest price allotted to dry lands was $25 an acre.

With adequate water rights the land valued at $125 an acre

should be valued at $150. An adequate water right on $25 dry land will make it worth $125 an acre. 160 acres of Phebe Strong ranch valued at $5 an acre, better land than in item 2, Exhibit 20. Applied $5 per acre on the upland pasture of the Phebe Strong ranch; the Wm. Strong ranch, valued 15 acres at $50 an acre, 25 acres at $125 an acre, 27 acres at $125 an acre, 50 acres at $15 an acre, 95 acres at $125 an acre, 25 acres at $14 an acre, 39.4 acres at $20 an acre, 3.6 acres at $10 an acre. The acreage was estimated. Skouland gave some information; Skouland went somewhat into detail. Highest value per acre was $125 on irrigated lands and this was due to the character of the water right, as in the case of the Phebe Strong ranch. Becky Archer ranch, 100 acres at $125 an acre, 17 acres at $10 an acre, 12 acres at $75 an acre; 16 acres at $25 an acre; 5.6 acres at $10 an acre; upland pasture valued at $10.

No irrigated land in the ranches was assessed higher than $125 an acre; because of the water right. Frank Archer ranch, item 12, 260 acres at $125 an acre, 67.6 acres at $25 an acre, 160 acres at $5 an acre; cannot tell where the $25 acre land was; 160 acres upland pasture at $5 an acre. Item 13, Mountain reservoir site, some like tract 2, and some like tract 3; would be called mountain pasture, not as good as some of the other, but better than the stone quarry placer claims; assigned the standard pasture land value of $5 an acre.

Item 14 not valued; did not see the headgate to the Harriman ditch and omitted that item; did not value item 15, Harriman lake; valued some land around it, about 39 acres, at $1365; does not appear on Exhibit 20.

Item 16, Marston lake flume; land is fairly good, would have been if flume was not there; flume runs through good irrigated land, and the land where the flume is located is of the same class, but valued it at $30 an acre; did not take the value of it as a right of way into consideration.

Thinks land on either side of flume without water right could be bought at $30 an acre; would not want to give a price on that land with water right, but assuming they are good irrigated lands with an adequate water supply, and level, they are worth from $125 to $150 an acre; considered the fact that the Marston flume lands were in the form of a long strip, and not suitable for agricultural purposes; would be useless for a man to buy at any price.

527 Did not give any value to the land as a right of way, but deducted value because it was a narrow strip; valued some lands in item 17, Exhibit 20; can give no further information on it.

Did value parcel 14, item 17, 55 acres, at $1750, or about $30 an acre; estimated that acreage; was endeavoring to place value on lands in Marston lake site not under water; a few other such parcels were valued, amounting to about 167 acres, valued as dry land, but good land except it has no water right. Parcel 19, 16.84 acres, valued at $30 an acre; it is good land. Does not use $30 as a standard of value for land without water, but it is the value around Marston lake.

Impression that lands valued by him are outside of embankment; parcel 15, item 17, 20 acres, at $15 an acre, $426.60; don't think it would have been termed irrigable land, but is not positive. Item 17, parcel 20, 67 acres, valued at $30 an acre.

Don't recall whether he valued seeped land, or that a low value was assigned to any Marston lake land because of seepage; does not know what the water company paid for the land, and made no inquiry; does not know about sale prices in the vicinity; did not investigate.

Did investigate irrigable land two or three miles south and east of Marston; never dealt in lands in the vicinity of Marston or the Platte Valley ranches; only knows in a general way what lands sell for in those localities; dealings in land have been generally east of Denver and east of Greeley, and some under the Castlewood ditch; had 170 acres under the Denver Suburban Homes and Water Company ditch.

Lands purchased from Mr. Wall's company were to be supplied from the High Line and Antero reservoir. They are all practically disposed of. The lands east of Greeley were close to the Platte river, under the Lower Latham ditch and reservoir.

Lands in the Pleasant Valley district near Greeley have been sold at $200 an acre, excellent lands, with adequate water supply; raise all kinds of crops because of the reliability of the water supply; could raise just as good crops on lands east of Denver if they had reliable water supply; sold lands in Pleasant Valley for more than $200 an acre when times were good.

Times now abnormal; abnormally quiet; there is no market, but there will be. Now no market for anything except what a man has to have. Littleton Mill is item No. 18, Exhibit 20; never had any experience in dealing in lands in Littleton before making value of that item; made some inquiries at Littleton, not a great deal; talked with some parties, but don't know whom; did not ask their judgment about particular lands in item 18; assigned own values; Sul-
528 livan reservoir site, item 19, Exhibit 20, valued at $1000—prairie grazing land, valued at $12.50 an acre; useful for no purpose except grazing land; too high for any kind of a ditch; thinks the value is too high, and should have been $800.

Thinks grazing land near Denver may be worth $10 an acre.

Not more than a mile difference in the distance from the city of the Wall lands and the Sullivan reservoir.

Bought 4600 acres from Wall for $276,050; varied from $5 to $100 an acre; the $5 land was about twelve miles from the city limits, considerably farther away from the Sullivan reservoir. Another quarter section was sold at $6.25 an acre, all included in the large deal.

Item 20, Cherry Creek galleries, total value $4125; assigned no value to item 21, Exhibit 20. Item 22, Ashland Avenue pumping station, divided into town lots outside of City limits; has never dealt in lands in that vicinity; have had them put up to him for sale within a year; I think they were on Vrain Street about 29th.

Valued the first four lots at $100 apiece, $75 on the other seven.

The only way that he can justify value is to say that it is his judgment on the value of it, based somewhat on what people were asking for the lots at 29th and Vrain, and they were closer in. Made some investigation, but not to any great extent. Values on this property were "our own values." On the city property, deferred a great deal to Mr. Anderson; witness' specialty has been outside property.

Anderson told witness what the lots at 29th and Vrain could be bought for; the lots were not offered to witness. Recollection is that improvement taxes were to be assumed; does not know what they amounted to; thinks possibly between $40 and $50 a lot.

Item 23, De Lappe Place pumping station, valued at almost $150 a lot; they are curbed. The fact that the lots are located at a transfer point has an effect upon the value, making them available for small business purposes; did not take that into consideration. Item 24, 43 lots, Cottage Hill, inside the city limits, on a high and sightly point, valued at $2 a front foot, five being valued at $1 a front foot.

Has never dealt in property in the vicinity of Cottage Hill; there are no sales, to speak of, to use as a criterion; did not know that recently lot 33 in block 20 had sold for $175; does not know the location of the lots by numbers.

Did not know that three lots in block 23, Cottage Hill, sold recently at $175 a lot. Knowledge of such sales would not change witness' opinion, unless he knew the details. Witness thinks market value is what a piece of property would sell for, and not what was asked for it.

529 If witness was not able to get lots at the value he thought they were worth, the market value would be more than his value, and he thinks now Cottage Hill lots can be bought for less than the market value. Would understand market price to mean what a willing buyer would pay and what a willing seller would take for a piece of property; discusses market value.

Knows the John McDonough Securities Company; they deal largely in lots in that vicinity; did not occur to witness to inquire what they were doing in buying and selling lots in that vicinity; they are general dealers; does not know if they are the principal dealers. Witness asked home owners in the vicinity of Cottage Hill what lots were selling for; relied on Mr. Anderson's judgment more than on his own as to city lots, but had many controversies on values. Based his discussions on his knowledge of values. Witness' knowledge of values in Park Hill and Capitol Hill is of some value in putting price on Cottage Hill lots. There are some good buildings down in the vicinity of Cottage Hill lots on West 33rd Avenue; did not inquire from the owners what they paid for their lots.

Referring to item 25, visited West Denver Pumping Station; concurs with Mr. Anderson's valuation of $900; never had any dealing in property in that vicinity; based value on general information; made some inquiries.

Thinks lots are in Middaugh's Addition; cannot point out the different parcels one after the other.

Inquired from different parties in the neighborhood; don't re-

member asking the names; cannot tell who they were; don't know how many persons he inquired of; knows Mr. William Allen, but did not inquire from him; did not know he owned any property there; it takes approximately ten lots to make an acre.

If witness had known that Allen put a value of $10,000 an acre on his holdings immediately adjoining West Denver pumping station, does not know whether it would have changed his judgment. Would want to see if the property had any special value. Item 25, 9-¼ acres, being parcel 9, valued at $3000 an acre, part of West Denver pumping plant; based valuation on same experience; has had some experience in track property; had some recently put up to him.

Has not been buying for two or three years; knew the land had trackage, and took it into consideration. Item 26, tail race, given an acre valuation of $1500 an acre; parcel No. 10, $1000 an acre; parcel No. 11, $750 an acre.

Thinks tailrace is south of the West Denver pumping station, but cannot tell. Tailrace is inferior land—swampy and gravel beds; it is not of any value; it comes up to and adjoins land worth $3000 an acre; does not justify the value on what land was actually
530 selling for, but on the basis of what lands are actually worth; valuations made on lands just as ordinary real estate, without specific purpose in view. Thinks values put on the tailrace according to what land would be worth in the shape it was.

Does not think it is of much value as land, but that depends on the market value of lands in the locality. Took all the steps that were necessary to judge its value; the land is surrounded by trackage; did not inquire what manufacturing establishments paid for the land they are using, or what they were holding it at. Did make general investigation of all land down there; cannot tell what specific investigation was made. It is true that Mr. Anderson largely determined figures on West Denver lands; sometimes he wanted a higher valuation than the witness, who was a "bear" on it.

Parcel 10, item 26, is down near the river; put a separate value on each parcel in item 27. Cannot locate parcel 17 of item 27. When witness was on ground, had a map with all the parcel numbers printed on it.

The value of $4545 placed on parcel 17 was the value used when the witness had the data before him; cannot state the basis of that judgment, except that some inquiry was made; it was based on their own experience; made some personal investigation, but cannot state how inquiries were made; does not know who owns the strips on either side of parcel 17; did not know Bartels Brothers owned it; phoned to Bartels and Anderson phoned him, but got no information; amount that was asked for both sides was apparently the same; witness does not recall; tried to get Bartels, and never got him; don't know whether it is Bartels, the lawyer; have forgotten which Bartels it was. They told witness nothing. Got no information from them to the effect that the land was worth $1500 an acre. Bartels is the only name witness can recall, but did inquire from quite a few. Did not ask Mr. Bartels who was in the court room; never saw him

before; supposes that some of the $1500 came from his inner consciousness. Did not know that the water company purchased parcel No. 18 within recent years, nor that they paid $3000 for it. Will agree that any reasonable price would be all right if the water company needed the land and ought to have it. If they were willing to pay $3000 an acre, it was worth that to them.

Such a piece of land would be worth anything up to a reasonable amount, according to what it was required for. Witness valued it as land. Parcel No. 19 valued at $1500. Did not know it was near D. & R. G., and did not inquire of D. & R. G. Made other inquiries, but cannot recollect from whom.

531 Parcel 20, 17 and a fraction acres, valued at $750 an acre. Only knows in a general way where it is located. It is south of a parcel that was valued at $1500 an acre. It may adjoin it; does not know; cannot tell why the difference in acreage value was arrived at. Is not very well informed right now, without the data which he had at that time in making valuation. Does not know where the map is that he used; ought to be on the ground with the map before him.

Witness has forgotten who told him about the values, but thinks he could get more data to the same effect. Cannot name a single person from whom he inquired or telephoned. Mr. Anderson did most of it. Mr. Anderson inquired by telephone, and witness only had use of that information as Anderson told him.

Parcel No. 22, value at a little less than $700 an acre; parcel No. 23, at a little more than $600 an acre; parcel No. 21, at $750 an acre; was not aware that those three parcels were purchased by the water company from Mr. Middaugh at $5000 an acre. That price for a right of way may be all right, but not as land. Thinks he could buy lots in Middaugh's and adjacent additions at $50 a lot.

Made some investigation largely through Mr. Anderson's telephone conversations, but does not know what the answers were. Parcel 24, 20 acres, valued at $12,600; does not know whether it adjoins parcel 19, which was valued at $1500. Cannot tell why there was a difference in acreage valuations between parcels 19 and 24.

Did not inquire from Phillip Ryan, who owns property adjoining; does not know where Bailey's addition is.

Does not know whether inquiries were made about lots in Bailey's Addition; does not think that lots would be sold in that addition for $250 to $300 a lot; has not a clear notion where parcel 25 is; valued it at $225 an acre, close to the river, and the river runs through it.

Does not know that the Western Chemical Company sold land adjoining it at $1000 an acre. Would not undertake to say what inquiries were made about it. Parcel 26, 8 acres, valued at $2500, approximately $300 an acre; does not know what addition it adjoins.

Does not know that lots have recently sold in Richthofen's Addition at $1500 an acre. Made no examination of the recorded deeds from the different localities; did not go to the court house; don't know whether such knowledge would have affected his judgment. Instructions were to value the land as land, and not take into con-

sideration its value as right of way or any thing else. If I
532 appraised as a right of way, value might have been increased eight or ten times. It would be important to know the sale prices for adjoining ground.

Witness took steps to ascertain the different sale transactions mentioned, but did not find them. If witness ever heard of them before, he has forgotten them. Parcel No. 27, valued at $300 an acre, total $1500, or at a rate of $30 a lot; adjoins Norwood Addition; this parcel faces Alameda Avenue.

Does not remember the condemnation suit in which similar property was taken; condemnation occurred within the last three years; parcels were valued in condemnation which were taken right out of parcel 27; valued in condemnation at $200 a lot; in condemnation a right of way value is allowed.

Values allowed by witness were without regard to condemnation value; has no idea what allowance was made in the condemnation suit. Parcel 28 adjoins parcel 27 on the west, and also faces Alameda Avenue. Assigns a value of $150 an acre to parcel 28, or $15 a lot.

Thinks he would undertake to buy lands in the neighborhood at $150 an acre; bases his judgment generally on the same considerations. Parcel 30, 16 acres, valued at $2250, or about $150 an acre; some of it approximately valueless from land and real estate standpoint, as it is part of the bank of the river; it is not valueless as river bottom, but is as land. There are good gravel beds being operated in the vicinity.

Entirely eliminates any gravel value.

Knows where the Sutton, Steele Manufacturing Company's plant is, immediately to the east of parcel 30. Did not inquire what they paid for their property, or what they held it at; didn't know that in October, 1912, they paid $2000 an acre for it; did not know that thereafter they purchased an additional strip of ground at approximately $6000 an acre; did not make sufficient inquiry to ascertain that fact; did not know that the Colorado & Southern held ground immediately adjacent to parcel 30 at 14 cents a square foot. Item 27, parcel 31, 20 acre-tract, valued at $300 an acre.

Made no inquiry as to the value of land in the vicinity; thinks that his value was assigned partly because lands in immediate vicinity were used for garden truck purposes; did not know that the garden truck lands in that vicinity could not be bought for less than $1000 an acre; made no particular inquiry with regard to this tract. Parcel 32, 6.06 acres, valued at $900, just half the price put on the adjoining parcel to the north; thinks the parcel to the north would be cheaper at $300 than parcel 32 at $150 an acre. Parcel 32 is just a long strip of land, and as land would not be worth much. The
533 fact that it is a long strip of land has something to do with its valuation, and that was taken into consideration. The same is true of parcels which constitute items 25 to 27, generally; they are less valuable because they will not readily plat into lots. The fact that they are of a shape available for the uses to which they are now put reduces their value according to the basis applied by the witness.

Parcel 32 runs through gravel beds, but the gravel value was not considered; has no familiarity with the value of gravel lands or the royalties paid. Parcel 33, 13 and a fraction acres, valued at $100 an acre; land is absolutely valueless as land; worth more as a gravel bed; it is in the midst of proven gravel ground; don't know what the prevailing price of gravel is; thinks it is 10 cents a cubic yard; thinks the land is worth $15 an acre for gravel. Parcel 34 lies just at the end of parcel 33; appraised a quarter of an acre at $75, or on the basis of $300 an acre.

Supposes there is some reason for making a difference between the acreage value on parcels 33 and 34, but cannot remember. Considering parcels 25, 26 and 27 together, gave no consideration to the fact that the land had been assembled into shape, making it available for right of way; it has value on that account, and also for the use to which it is put by the water company.

Total acreage of items 25, 26 and 27 is about 149 acres, the total value of which is $91,776; for right of way purposes it would have a much greater value—perhaps five times greater.

Does not think if someone tried to reproduce the strip of territory shown on Exhibit A-4 it could be done for $91,776; it would cost perhaps $400,000 or $500,000. Values given by witness do not include so-called overhead expenses; nothing is allowed for cost of going out and getting the property; no consideration given to interest during construction.

Items 28, 29, 30, 31 and 32 were valued on the same principle. Item 34 was not valued. Witness had nothing to do with the conduit lines, but did appraise the 20 acres at Loretto Heights.

The value of the 20 acres at Loretto Heights is reduced by presence of conduit line, which makes it less valuable as land; did not value items 35, 36 or 37; knew that the lands on Exhibit 20 had been valued by a board of appraisers appointed by the city and by the company in the year 1909. Had those values before him all the time.

Does not think the appraisement made at that time had any weight. Considers he is better informed on farm lands than city property. Some of the reservoirs, rights of way and lands
534 of that sort testified to by the witness are laid out and have been acquired for water works purposes.

The West Denver lands have greater value for purposes for which they are used than that placed on them by witness.

EDMOND C. VAN DIEST.

Direct examination:

Mining and civil engineer; graduate of Colorado State School of Mines in 1886. From 1886 to 1903, in charge of Sangre de Cristo Grant. From 1903 to 1909, engaged in development work for Gen. William J. Palmer. During that period carried out work, and designed a large portion of it, in the way of all classes of improvements—water system, steam heating system, electric plant, park construction, river improvements, and various other classes of work,

amounting to something over two and a quarter million dollars. From that time to present engaged in consulting and private interests in connection with Central Construction Company, constructing all classes of work, including reservoirs and water systems, sewer systems, pipe-line work, manufacturing of concrete products, and construction, operation and management of electric and heating plants. Personally interested in electric light and heating plants in Colorado, Wyoming and Nebraska, and have examined into their valuation in connection with purchase.

Member of the Committee of Engineers appointed by Public Utilities Commission to investigate and report upon plant of The Denver Union Water Company, of which Mr. Fellows was chairman, C. P. Allen and witness being his associates; appointed August 6, 1913, work completed January 17, 1914. Valuation made on a purchase basis.

Committee adopted plan of valuation by grouping different classes of property, enlisting services of gentlemen deemed experts for the valuation of elements—for buildings, George Walter Brown, Appraiser of Rocky Mountain Fire Underwriters' Association; equipment, J. N. Flood, of Hendrie & Bolthoff; steel work, Herbert S. Crocker, construction engineer; wood stave conduits, William F. Allen and T. J. Murphy, contracting engineers. These gentlemen in each instance instructed to list property at actual net cost of labor and material. When they made their reports, items were gone over, tabulations made up and totals drawn from different lists. To the various schedules as returned by them "we added ten per cent for engineering, and fifteen per cent for contractors' profit, overhead charges and items of that nature, contingencies, and also interest during construction at four per cent per annum for the average estimated period that the construction would require for each group."

Mr. Anderson and Mr. Carper valued the lands, listed in two schedules, one for lands outside the city, the other for lands within the city. They made valuations on these lands with the exception of lands covered by reservoirs and the filter plant. The schedules were as follows: Schedule A, lands outside of the city; Schedule B, lands inside of the city, valued, with the exceptions mentioned, by Anderson and Carper; Schedule C, structures, including reservoirs, filter basins, filtration plants, with the exception of buildings etc., valued by the Committee; Schedule D, infiltration galleries; Schedule E, conduits, valued by Allen and Murphy; Schedule F, mechanical equipment, by J. N. Flood; Schedule G, distributing system, by the Committee; Schedule H, buildings, structures and connections to buildings, by George Walter Brown; Schedule I, stock, prices, or values by Mr. Flood, assisted by Mr. Angell; Schedule K. miscellaneous, including corrections to other schedules and miscellaneous properties, by the Committee.

The several experts were employed to make up cost values on various classes, because of their special knowledge, and to save time.

Exhibit 19 is a copy of the summaries from the report made by our committee of engineers. Schedules C to I are the schedules made

up from the work of the several experts. The column "Replacement Value" contains the figures reported by the particular expert employed, plus the allowance made by the committee of engineers, costs, contractors' profit, overhead charges, interest during construction and contingencies. The column "Depreciation" shows total amount of depreciation against each item. The column "Percentage of Depreciation" shows the percentage applied and the last column shows the result after deducting depreciation.

On certain classes used the life table, on others estimates were made of serviceable life of individual elements. Life table for larger elements of property as follows: cast iron pipe, 3 and 4 inches 35 years, 6, 8 and 10 inches 50 years, 12 to 24 inches 75 years, over 24 inches 100 years; wood stave conduits 40 years; concrete lined tunnels and concrete work in reservoirs 100 years. Except as above stated, depreciation was determined for the particular article or particular class especially. For instance, where good care had been taken of the property the serviceable remaining life is more than the difference between the estimated life and the expired life. In
536 that case an estimate was made of serviceable life remaining and that was applied.

The depreciation was determined by the sinking fund method, with a view to complete amortization at the end of the useful life. Mr. Flood determined the remaining serviceable life for certain boilers and other items of equipment. Flood handled Schedule F, the major portion of Schedule I, and portions of Schedule K.

(Hre interrupted for other testimony.)

To the figures submitted by W. F. Allen, as shown on Exhibits 21 and 22, for the purpose of making up the figures in the first column under the head of "Replacement Value" in Schedules D and E in Exhibit 19, we added five per cent for engineering and fifteen per cent for contractors' profit and contingencies, and to the sum total of that figure interest during construction for the average of the estimated period required for the construction at the rate of four per cent per annum. In those schedules depreciation was deducted on the basis of an estimated life for the wood stave conduits of 40 years.

In Exhibit 19, the valuations in the various schedules were arrived at as follows: Schedule A, major portion of valuations, except areas covered by reservoirs, submitted by Armour C. Anderson, and his valuations taken by the committee, the committee valuing areas covered by reservoirs. As to Marston Lake and Platte Canon Reservoirs, the lands were valued as lands with water. As to Lake Cheesman, the lands were valued at $25 per acre. Schedule B, same as Schedule A. In Schedules A and B improvements were valued by the committee, except certain buildings valued by George Walter Brown. On lands, to the best of my recollection, the committee accepted Mr. Anderson's valuations, except certain changes made in Schedule B. Schedule C, the details determined and listed by different assistants; afterwards cost values put on them and percentages added as in the other cases. These additions were,

first, engineering, contractors' profits and contingencies, then on the total item, including those allowances, interest during construction for the average estimated period. Schedules D and E were from W. F. Allen's figures, as already detailed. Schedule F started with Mr. Flood's figures and was made up in the same way. Schedule G made up by the committee and its assistants. The property entering into this schedule was carefully listed and checked, measuring up on the official city maps and checking back from block to block along the various streets throughout the entire city. Pipe sizes taken from Water Company records; checked up at some thirty different places where examinations later made. Pipe sizes and
537 date of laying pipes confirmed in many details by C. P. Allen, who had been chief engineer and had an intimate recollection of the periods of construction.

Schedule H practically all by George Walter Brown, to whose figures the committee applied certain percentages. Schedule I by Mr. Flood. We did not consider it proper to apply any depreciation to Schedule I, as it was practically new material. Do not know whether anything was applied to schedule on account of handling, placing in stock, cost of transportation or the like. That was in the hands of the assistants, and they will have to testify in detail in regard to it.

Schedule K:—under this, "Office Equipment" includes office furniture, miscellaneous material in the offices, including the sanitary laboratory; second and third items, equipment at ranches; third item, crops, alfalfa, grain and various like items; next item, nine automobiles, valued by Mr. Flood; telephone lines, cost of construction estimated by Mountain States Company. "Miscellaneous" includes various items omitted from other schedules. The next is corrections in Schedule E, which have been carried into Exhibit 22. Schedule K may be denominated a schedule of addenda and corrections. On account of the haste constantly urged upon us, we did not have time to classify them properly.

Exhibit 23 is a summary of the various schedule summaries of Exhibit 19. Page 1 indicates valuation of property, without inclusion of going-concern value or water rights, except in so far as these items have been included with land values. Page 2 is a detailed summary of the different schedules and net valuations, with a deduction of certain property not considered by the committee essential to the operation of the system at that time, the details of which deduction appear on the last page. Page 3 is explanatory of page 2.

Exhibit 24 is a tabulation or summary of the costs of the distribution pipe system, except culverts and river crossings, used by the engineers' committee, showing what was installed in each year, the replacement value, the amount added for engineering and incidentals, contingencies and contractors' profit, and interest during construction, making the total replacement value from which depreciation was deducted. There being no definite records available, all pipe laid prior to 1890 were included under the column marked "Prior to 1890." The net value of the distribution system as shown in Exhibit 24 has been used in other exhibits.

Exhibit 25 is a tabulation prepared at the request of Mr. Nye and contains his suggestions, and also is obtained almost altogether from the different exhibits of the Water Company. Exhibit
538 26 was prepared likewise at the request of Mr. Nye, and in the same manner as Exhibit 25. In Exhibit 25, page 1, first line gives total valuation as stated in Exhibit C. Then follows list of deductions as claimed by defendants' attorneys, either as excessive or as property not essential or as property not to be included in a rate case. The first item of deduction, difference in valuation of water rights, based on difference in quantity between safe yield as claimed in Exhibit C and average daily consumption for maximum year in second feet, at $5,000 per second foot. This is explained in Exhibit 26. Page 1 of Exhibit 26 is further explained on pages 2 and 3. We took the average consumption per day for the maximum year, 1910, added water for farming purposes for 950 acres, on the theory that 1¾ acre feet per acre was needed, and on the basis of an irrigation season of 214 days, and added reservoir evaporation for 1,700 acres, covering Platte Canon, Marston and Cheesman, at the rate of 6 vertical feet per annum, making a total of 94.03 second feet, which we valued at $6,000 per second foot, producing the amount mentioned on page 1, in item 1, of Exhibit 25.

In Exhibit 25, the second item of deduction is going concern value, deducted as not properly includable in a rate-making case. The third item is explained on page 2 of Exhibit 25. Item No. 3, page 2, of Exhibit 25, is explained on page 4 of that exhibit; item No. 6 on page 5. On page 1 of Exhibit 25, item No. 4 is shown in further detail on page 6 of the same exhibit. Exhibit 25, page 1, item 5, is explained on page 7 of the exhibit. Item 6, page 1, is difference between assessed value and Exhibit C value on Lake Cheesman lands, the assessed valuation being approximately $114,120.

Item 7, page 1, Exhibit 25, is depreciation on basis of $138,000 per annum, less new construction as shown by Exhibit Z. Item 8, paving over mains as included by the Utilities Commission engineers. Exhibit 25, page 3, Schedule A-1 explained. The items covered by Schedule A-1 were eliminated in the report to the Utiliites Commission. The opinion of the committee at that time was that they were properly excluded. Exhibit 25, page 4, Schedule A-2 explained. All the items in Schedule A-2, with the exception of Lake Archer and canal, were deducted by the engineers of the Public Utilities Commission in their report, but Lake Archer and canal were not included for deduction in that report.

Exhibit 25, page 5, Schedule A-3 explained. Part of items in Schedule A-3 were deducted in the report of the Public Utilities engineers and part were not. Still of opinion that those then deducted should be deducted. One item here deducted and not deducted in the former report is Lake Archer canal and Mississippi Street con-
duit land; another is the ranches. The first is here deducted
539 on the theory that the turbine equipment is obsolete and not necessary for proper operation, because there are two other pumping units, each capable of handling estimated capacity of that station. The ranch lands are here deducted because it was not con-

sidered that they were necessary to proper maintenance of water rights.

Exhibit 25, Item 6, Valuation of Corporation Cocks, taken from Exhibit C.

For purposes of Exhibit 25, depreciation determined by taking five-twelfths of $138,000, being annual depreciation mentioned in some of plaintiff's exhibits, from this deducting new construction per Exhibit Z.

Exhibit 27 is also a tabulation prepared by witness at request of counsel. It is a tabulation showing the net return upon various assumptions as to rating base, operating expenses, and taxes, etc., on the leaflet schedule and also with a twenty per cent reduction therefrom. Witness explains the same. Page 2 shows the estimated rate of increase in net return and various percentages of depreciation, determined by the various amounts referred to in Exhibit A-19. Page 3 of Exhibit 27 is a recalculation of Exhibit A-19, Table 2, using 6% return and 1% depreciation. Method explained. Next page of Exhibit 27, being a revenue statement, explained. Figures in column headed "Interest" were shown on statements supplied by Denver Union Water Company during time of examination by witness' committee. Last page of Exhibit 27 shows profit on taps, with accretions at 4% compound interest; basic figures being from some published reports and some reports supplied by Water Company during our committee's examination.

The ten million dollar rating base used in Exhibit 27 is approximately the figure of net value of serviceable property shown on Exhibit 25.

The sixteen million dollar rating base is approximately the figure shown in Exhibit C.

The assumptions as to percentages of net return in future years stated on page 2 of Exhibit 27 are upon the theory that increases in revenue can be secured without increasing the installation beyond or in excess of amount of annual depreciation. That is to say, no increase of capital invested.

Exhibit 28 contains the detailed sheets used by our committee in connection with cost of distribution system, summarized in Exhibit 24, and are copies of the corresponding sheets in the report made to the Public Utilities Commission.

Referring to Exhibit 25, page 5, Item 27, inasmuch as we eliminated the mechanical equipment operated by the water power, think we should also have eliminated valuation we placed upon that portion of the lands. Whether Mississippi Street galleries and
540 conduit should be eliminated, express no opinion, but it would be unnecessary to retain more than land for a right of way for the conduit, "if it were possible to dispose of remaining lands at values shown here."

Have made no investigation and reached no determination as to the value of the water rights.

Assuming that all of the deductions shown on page 1 of Exhibit 25 should properly be made, net value of serviceable property for rate making purposes would, on basis of that assumption, be $10,135,379.

Except as to details of distribution system shown on Exhibit 28, I have no details on other schedules. These were left in the office last January, and apparently have been inadvertently destroyed.

Exhibits 23, 24, 25, 26, 27 and 28 offered and admitted. Exhibit 25 being admitted over objection and exception specifically made. Exhibit 26 being admitted over objection and exception specifically made. Exhibit 27 being admitted over objection and exception specifically made.

Cross-examination:

Associates on committee were A. Lincoln Fellows, a member of the Public Utilities Commission, and C. P. Allen, formerly one of the engineers of The Denver Union Water Company. This committee appointed by Public Utilities Commission, by resolution, "for the purpose of making a careful investigation of the present value to the City of Denver of The Denver Union Water Company's holdings."

Committee received no legal advice, although it sought it.

Committee valued only the physical or tangible property. All intangible values excluded, because there were certain legal points which we were not certain of, and we did not have sufficient time for investigation of the subject. We desired legal advice and could not obtain it. When we got through with physical values, we were not given a moment's more time to complete the other details, and never arrived at a conclusion as to whether the intangible values ought to be excluded or included.

Value on water rights omitted entirely, except insofar as they were included with farm lands.

Going value, or going concern value also omitted, though there was no definite determination that it should be.

Am not in a position to state the value of the water rights, assuming that they are owned by the Company. They are a very valuable asset.

My personal opinion is that in a rate case going value, or going concern value should not be included, but if, as a matter of
541 law, it should be included, it would involve a considerable addition to our valuation.

Except for an item of development expense shown on Exhibit 23, our committee confined ourselves, for the reasons stated, to the physical and tangible elements of the plant.

Exhibit 19, Schedule A, total value assigned by us to Lake Cheesman lands $36,299, by an error in addition is shown in Exhibit 19 as $35,784. Otherwise the engineers have taken into Exhibit 19 as the value of Lake Cheesman lands the values shown by Exhibit 20. Anderson fixed values outside of reservoir at two fifty per acre, and the committee accepted his valuation without investigation. The committee applied $25 per acre to the lands in the reservoir, having no regard to the fact that Anderson had fixed two fifty per acre for the lands surrounding it.

Witness has had some experience in purchase of reservoir sites, but not in that locality. Have been offered American Reservoir, but that is located in a forest reserve, and the site can not be obtained at

all except by special act of Congress. I do not know the condition of the title. What was offered me was certain bottom lands and the filings, for what they were worth. I do not know how large a portion of the area was covered by the bottom lands held in private ownership, but it was comparatively small. No work had been done on the American Reservoir, only the filings made. I am wholly unable to state whether the filings on the American Reservoir possessed any value whatever.

The original cost of Cheesman Reservoir site was not considered by us in determining the value of $25 per acre.

I have some knowledge of the Noxon site on Tarryall Creek. About three years ago I had an offer of that site. Noxon, the owner, was very hard up. Do not remember exact location of Noxon site, and have never been at it. I loaned Noxon money, which I never got back. The reservoir site was on either Lost Park or Tarryall Creek. Noxon was very much involved financially.

Also had in mind in connection with the $25 per acre valuation the Camp Creek reservoir and the Glen Eyre reservoir. The latter is a small reservoir for domestic and irrigating water supply for Glen Eyre, General Palmer's estate, for which he acquired 320 acres of land, of which 25 or 30 acres is covered by the reservoir. The price paid for that 320 acres of land is not the basis upon which the $25 per acre was determined.

Also had in mind reservoir of the Hydraulic Electric Company near Colorado Springs, up by Green Mountain Falls. The company failed to purchase from the owners of the lands, and the city bought lands within the reservoir site. I do not remember the area
542 submerged in that reservoir. It was never built.

In determining value of $25 an acre did not include cost of explorations and borings, amounting to twenty-five or thirty thousand dollars. That would be covered by our item of development expense on the whole system. All matters of that kind were intended to be covered by the general item development expense.

The reservoir sites which I have mentioned are comparable in a general way only with Lake Cheesman.

The Hydraulic Electric Company expended a great deal of money without acquiring a reservoir site at all, all of which would have to be added to the cost of the site.

In the case of Mr. Noxon, he was engaged in litigation or negotiations for years, and then did not succeed in acquiring the lands, and all the costs which he had incurred, and all the sums which he had spent would have to be taken into consideration in determining the value. However, I think that all of those things are elements of value attaching to the water rights rather than the land value. Water is the real element of value in connection with a reservoir site.

I do not remember any other reservoirs which we had in mind in fixing the value of Lake Cheesman. There are other reservoirs on the South Fork of the South Platte that I have not mentioned—the Twin Forks, or Allen and Maloney, reservoir, the Eagle, or Rhodes, reservoir, and the Bates reservoir. Made no investigation to ascertain what these reservoir sites could be obtain-d for.

The Cheesman site is an exceptional site, and possesses exceptional advantages, because of its location, lying below the mouth of Goose Creek and above all irrigable land surrounding Denver; because of the relatively small dam construction necessary; because natural stone abutments exist, and because of other like matters. On account of these "it has an exceptional value. That added value is really an item that goes to the water, as I understand it, rather than to the land itself." All values arising from such things as those mentioned above are, therefore, not included in the value of $25 per acre for the lands, because we did not value the water rights.

The $25 per acre represents the value of the lands as bottom lands only, with no addition on account of availability or desirability as a reservoir site. Water right values were omitted by us because of lack of time. We valued the land as land only. Our valuation was exclusive of water rights, and therefore we failed to include any additional value of the land on account of its adaptability for reservoir purposes.

543 The tables presented by us here in the form of exhibits cover these things only: First, values of land, as land, without regard to the added value thereof, if there be any such added value, because of the peculiar adaptability of the land as a reservoir site, or its peculiar advantages for that purpose or other like purpose; second, our estimate of reconstruction cost, less depreciation of structures; third, an estimate of something which we have called development expense, amounting to three hundred and odd thousand dollars. That is all these estimates presented by us include, and nothing more.

I think paving over mains should be included and not excluded, as we included it.

I think whatever value the water rights have should be included. Whatever the water rights are, I think they should be added to our estimate, but would not undertake to say what that value is. That value would include the added value of lands for reservoirs.

I am acquainted with the Nederland Reservoir of The Colorado Power Company, but made no investigation as to what the site cost in making the determination as to the value of Lake Cheesman lands.

Our total valuation on Lake Cheesman lands and structure was a little over $1,200,000. It is my belief that Lake Cheesman as an entity is worth more than that sum. The $25 per acre price for Lake Cheesman land was applied to 675 acres. If the submerged acreage is 874, a correction should be made.

We gave no consideration to the fact that the old board of appraisers valued the Lake Cheesman lands at $200,000. At the time of making the valuation we did not know that those lands were assessed for taxation at a value of $114,000, as shown by my exhibit 25, page 1, item 6. The lands outside the reservoir at Lake Cheesman were valued by Anderson. With the limitations stated, we adopted Anderson's valuations on the lands. I did not attempt in any way to examine any of these lands from the standpoint of land values, nor do I consider myself competent as to land values. Our acceptance of Anderson's values was based upon the assumption that he had

returned fair values on these lands, and I have no means of forming an independent judgment of my own upon that subject.

As to Platte Canon intake lands, we added nothing on account of its availability for the purpose of intake works, and did not investigate the question of its value for that purpose.

The items listed under the heading "Improvements" in the land schedules contained in Exhibit 19 are for the most part fencing and like improvements.

544 We added nothing to Anderson's values of lands used for sedimentation basins or filter beds on account of their adaptability for that purpose.

We valued the land in the Platte Canon Reservoir at $70 per acre.

Apparently, as shown by our exhibits, no valuation has been attached to parcel No. 6, Douglas, 10.30 acres.

The land in the Platte Canon Reservoir was valued as irrigated land with a rather indefinite or uncertain water right. If we had valued it as land with an adequate water right, the value per acre would have been higher.

I do not claim to be versed in real estate values. We had to assume some values for these lands, inasmuch as Anderson did not value them, but I do not claim to have any special knowledge on the subject.

Our committee valued the lands in the Platte Canon Filter site, Anderson did not. We fixed the value at about $60 per acre. I do not know why we applied a less value to that than the lands in the Platte Canon Reservoir. I do not know whether any addition should be made on account of adaptability.

Item 6, Exhibit 20, Platte Canon Power House site, Parcel No. 4, Jefferson, we adopted Anderson's figures. Do not know the basis of his valuation. It would be at the rate of about $33 per acre. I know of no reason why that land should be worth less per acre, as land, than the land in the Platte Canon Reservoir site or in the filter site. It immediately adjoins the filter site.

Item No. 7, Exhibit 20, being parcel No. 5, Jefferson, 20 acres, valued by Anderson at $1,300 and that value adopted by us. That would be at the rate of $65 per acre. I presume it adjoins the land in the Platte Canon reservoir, or the land in the filter site, or the land in the power house site, and know of no reason why it should receive a different valuation as land.

As to the gallery lands above Lehow Lake, we adopted Anderson's figures and gave no consideration to the question whether value should be added for adaptability. Would not say that such value ought not to be added.

The committee placed valuation on Lehow Lake at the rate of $30 per acre, in same general neighborhood with other lands on which higher acreage value was placed. Do not know why we assigned a lower value per acre. Think we added nothing for adaptability. The lands immediately above are Tract 5, Jefferson, Sheet 1, Schedule A, Exhibit 19, and were valued at $65 per acre.

Of the lands described up to this time, we included water right values only in respect to the lands in the Platte Canon Reservoir.

Item 14 of Exhibit 20, being parcel No. 26, Jefferson,
545 which appears in our Exhibit 19 on page 2, apparently was not valued. I think the exhibits should be corrected in that regard. Upon investigation I find that the item was inadvertently omitted. It covers the headgate of the Harriman Ditch.

We included nothing in our estimate on account of the Company's ownership in the Harriman Ditch. As stated, we omitted water right values, but something should be included in our estimate on account of the Company's interest in the ditch structure of the Harriman Ditch, which is used to convey water to Marston Lake.

We included nothing on account of the Company's ownership of an interest in Soda Lakes. Assuming that Soda Lakes is used for reservoir purposes in connection with the Water Company's plant, something should be added to our valuation on account of the structure therein, even though water right values be excluded.

We have included nothing in our valuation on account of the Company's contract with the Harriman Ditch Company for the construction and use of the enlargement of the ditch. Even though the water right values be excluded, the structural value thereof should have been included in our estimate.

Item 17, Exhibit 20, Marston Lake Reservoir, Anderson valued only a few of the several parcels of the reservoir site, the remainder being valued by our committee. Out of the total of 840.224, Anderson valued 167.51 acres, leaving 672.714 acres valued by our committee, upon which we placed a value of $119,565, or at the rate of about $170 per acre. The parcels valued by Mr. Anderson were intermingled with those valued by us, but he valued them at the rate of $28 per acre. I cannot account for the difference in rate. We valued the lands in that reservoir as farm lands with an adequate water right for irrigation purposes.

As previously stated, I have no knowledge of or experience in real estate or land values in this vicinity. I have bought or sold or otherwise dealt in lands of that sort in recent years. In the case of Lake Marston, the value assigned to the lands was strictly a value as irrigated lands, without any regard to the fact that they were in a reservoir, and without any regard to adaptability or desirability for reservoir purposes. These lands were irrigated farm lands when the Company acquired them for reservoir purposes. I do not know when the Company acquired the lands, or what they paid for them, or that they were obliged to condemn portions of them, or that they were obliged to pay in addition to the
546 ordinary or specific land value considerable additions on account of special adaptability for reservoir purposes.

All of the cost of assembling the lands in such a reservoir, the cost of acquiring the same, the interest on the investment therein, the cost of condemnation, the extra cost involved in acquiring irregular pieces, and all other like costs would be included in development expense, according to the figures presented in Exhibits

19 and 23. I recognize that all such costs must be taken care of, and the item into which we have thrown all such costs is the item "Development Expense" appearing in Exhibit 23.

As to item 20 in Exhibit 20, the Cherry Creek Galleries, our committee adopted the valuation of Mr. Anderson, adding nothin- for adaptability. The adaptability of the galleries for the purpose to which they are devoted is an element of water right value, and therefore we have not added it, because we did not include water right values.

Exhibit 19, sheet 4, tract 1, the total value should be $6,800 instead of $2,800. That item is included in our deductions, and $8,243.40 deducted on that account. There is some mistake there.

The Cottage Hill lots occupy a high point and include the Cottage Hill tank site, but we added nothing to the land values on account of special adaptability for that purpose.

Exhibit 20, items 25, 26 and 27, the West Denver lands, the committee did not accept Anderson's valuations. We thought his valuations were too low. I do not know what price or valuation we adopted as to those lands. I cannot state how we happened to hit upon these particular values, as shown by Exhibit 19, for those items. It was specifically brought to the attention of the committee that Anderson's valuations were too low; thereupon the matter was discussed and these other figures shown by Exhibit 19 placed upon the property.

If our attention had been specially directed in that regard to some of the other of Anderson's valuations, we might possibly have been inclined to make similar changes.

As to these West Denver lands, the values as adopted by us appear in Exhibit 19, Schedule B, beginning with item or parcel 9. In this Schedule B of Exhibit 19, the figures set down under the heading "Land Values" are those returned by Mr. Anderson, and under the heading "Total Values" those made by the board of engineers. No improvements are included in any of the figures in this schedule. In some instances we reduced Anderson's figures; I do not know why.

Do not know why we adopted an acreage valuation of $3,200 an acre for part of this ground. Did not know that Holme
547 and W. F. Allen, who is a son of C. P. Allen one of the members of the engineers' committee, owned the adjoining tract and held it at a valuation of $10,000 an acre. Do not know why we made other reductions in Anderson's values.

Exhibit 19, Schedule B, tract 20, do not know how we arrived at a value of $420 per acre. Think it was a clerical error in writing down the total for that item. Considering the value per acre placed by our board upon surrounding lands, it would seem to be a clerical error.

I cannot say why we increased to the extent that we did such of Anderson's valuations on the West Denver lands as we did increase.

In respect to these West Denver lands, as in respect to the other lands, we included nothing for the cost of assembling, or other like added costs.

The values at which we finally arrived for the West Denver property, covered by items 25, 26 and 27, were in our judgment the land values only, based upon the market value of adjoining lands, without the inclusion of any sort of additional cost or overhead.

Exhibit 20, items 34, 35 and 36, being rights of way for conduits; these are conduit rights of way owned in fee, valued by the committee and not by Anderson, at a total valuation of $6,520, at an average rate of approximately $50 per acre. We did not go over these conduit lands from the standpoint of real estate value. This $50 per acre was considered by us a fair average.

I have had a very limited experience in the acquisition of rights of way.

We added nothing to our values on account of added cost of acquiring narrow strips of land for right of way, or for the cost of assembling a right of way, but based the value per acre upon the per acre values of adjoining lands.

To the rights of way not owned in fee we assigned a value of $3,815. We did not go over them in detail, and do not remember the total length. 58 miles is approximately correct. Presume large portions of these rights of way are in county roads. We attached a value of the rights of way on county roads, but only the value that we thought at the time was a fair one for securing the rights. We based it upon the probable cost of securing the rights, particularly in county roads, assuming that the county commissioners would probably donate them. About all I can state relative to these rights of way is that we assigned that value, and I do not remember why. I would not be able to state now on what we based it.

548 Exhibit 19, Schdule A, Tract 7, Arapahoe, an 80 acre tract valued by Anderson at $1,000, but no value set down for it in Exhibit 19. We left it out because we did not desire to include it or the structures upon it; because we would have had to have deducted it afterwards if we had added it in, because we did not consider it used or useful.

In land values, Exhibit 19, Schedules A and B, we included nothing whatever on account of overhead expense, or on account of interest during construction.

In reproducing this water works plant, one of the first things necessary to be done is to provide the necessary land. The period of construction would be one year for plans and four or five years for actual construction, making a total of five or six years. During the period of construction the investment in lands would be making no return; that would be an overhead charge, a development expense.

Interest during construction upon the lands is analogous in principle to interest during construction on the structures. In our estimate of the reproduction cost we have included interest during construction in respect to the structures, but we have not included it at all in respect to the lands. We failed to include in the cost of reproduction interest during construction on the lands

because we were not able to determine it with the same definiteness as interest during construction on the structures. We could not make up our minds on the subject. It was one of the matters that we considered might be properly included under development expense. It was considered development expense would include that. Such development expense being the item appearing under that name in sheet 2 of Exhibit 23. That was intended to cover all those items of extra cost that we did not specify with definiteness.—overhead charges, legal expense, certain items in getting the business, and things of that sort.

As to interest during construction on lands, have understood that in the case of the Los Angeles aqueduct it represented 20% of the total cost of the lands. In the present instance the item of interest during construction would be a very large item.

Overhead expense is not included in any of our items of land values, with the possible exception of rights of way not owned in fee, which is a relatively small item. It costs money to assemble such bodies of land. This would be an actual out-of-pocket cost. Ten per cent on the prices paid would be a little high as an average for these overhead costs on lands, according to my off-hand view,
but it would approximate that. It it were eight per cent,
549 the total amount on our land valuation would be $40,000,
and our item of development expense would cover that, as well as interest during construction on the lands.

There are also carrying charges in connection with the lands before the plant begins to produce, such as taxes, which are actual out-of-pocket costs and must be taken care of somewhere in the reproduction costs. That also must be included under our item of development expense.

As to lands under the Platte Canon Reservoir, we added nothing on account of availability for reservoir purposes.

Whether we added anything for water rights to the lands under the filter beds I cannot say. I do not remember that detail.

Certain corrections in the items in Schedules A and B of Exhibit 19 noted and admitted, and corrected exhibits to be supplied.

We made no allowance for water rights values except in the following instances: As to lands in Platte Canon reservoir, valued as land having an indefinite and somewhat uncertain water right; land in Marston Lake reservoir, valued as land having an adequate water right, or one similar to the surrounding lands; possibly also as to lands under slow sand filter beds, and also certain portions of the ranch lands.

As to ranch lands, we took values as given by Anderson and Carper, with such allowance for water rights, and with an allowance for water rights of such character as Anderson and Carper have explained in their testimony.

As to interest during construction, we estimated that on all the structural parts of the plant and included it in the reconstruction cost, but we did not make such a computation or estimate in respect to the lands. As to structures, we made that computation on an average or net basis of 4% per annum, figuring that there would be a return interest on bank balances of 2%.

The subject of interest during construction was dealt with in our report to the Public Utilities Commission, which consists of two ponderous volumes, now in the court room upon counsel's table. In that regard we said in substance (exact language quoted in original transcript) that interest during construction is an actual cost which is a construction expense, and must be included in construction cost and replacement value; that four per cent bonds of the city can be sold at par; "this therefore specifies the rate." That construction, however, referred particularly to the construction of a new plant by the city. For the city's plant we did not assume any offset on account of interest on bank balances.

550 Of the total amount of expenditure, the rate of expenditure assumed was as follows: First year 5%; second year 10%; third year 20%; forth year 30%, fifth year 35%.

Report also stated that city might realize some interest from balances on hand, but no deduction was made on that account.

The report also stated on the next page that "This would be equivalent to interest on half the entire cost of labor and materials, lands etc., at four per cent for 3.4 years, or on the whole sum for 1.95 years." That quotation referred to the city's new plant. I think the word lands was inadvertently used. It was intended to apply to construction distinctly.

As to interest during construction on reproduction cost of Water Company's plant, that was computed on a basis of four per cent per annum for the average period. We used the same rate as for the city plant, because we considered that there was a return on a portion of the same of two per cent upon bank balances. We assumed that only a part of the money would be provided at first, and the balance from time to time as needed. Even then, some portion would lie in the bank and afford a return on balances. According to my assumption, money would be borrowed in installments just prior to the time of its being paid out. We assumed four per cent per annum as the net amount of interest during construction for the average period. To arrive at that we assumed some deduction from the gross rate on account of interest on bank balances. Do not recollect the details and cannot give them. I believe four per cent per annum as a net rate would be fair, and the committee so believed at the time of reporting, but I do not now recollect why.

As to interest during construction on the lands, some of the lands would have to be acquired at the beginning. According to good practice the lands, or the major part of them, are first acquired. In estimating reproduction cost of a water works plant, the assumption must be made that the constructor will acquire the lands, or the major part of them, at or near the inception of the enterprise. Consequently the capital invested therein would be idle practically through the entire period of construction, and there would be no offset on account of interest on bank balances to deduct therefrom. On the lands, the interest during construction would have to apply for a longer period than it would upon the various items of structures. The capital invested in the lands would be idle capital for a period of

five or six years. The major part of the capital going into lands would be invested for a construction period of four or five years. I do not think the rate of interest per annum would be less than six per cent. At that rate and for a period of four or five years, the interest during construction in the aggregate would amount
551 to from 24 to 30 per cent of the total amount so invested in lands.

One reason why we did not make an estimate of interest during construction on lands was because lands were valued at their present value. We also estimated materials and labor for the structures at present day values, but there we added interest during construction. Any one reproducing this plant would have to pay present day market values for the lands, as well as for the materials and labor for the structures. He would also have to stand the loss of interest during the period of construction upon present prices paid by him for the lands.

We thought interest during construction ought to be added to structures because they depreciate, but not to lands because they appreciate in value. I consider that a logical deduction.

I have already testified that I think interest during construction ought to be allowed upon the lands, and that our item of development expense was intended to cover it.

Possible increment in value of lands occurring between date of their acquisition and date when the plant begins operation ought to be offset against interest during construction on the investment in the lands.

I do not regard increment on lands as income.

According to my view, increment in land value should be included in the valuation of the property for rating purposes. Likewise, increase in value between time of acquisition and time of commencement of plant operation is an addition to capital.

If the increment in land value during the period of construction should not be offset against interest during construction on moneys invested in lands, said item of interest during construction would be a large item to be added. According to our basic valuation of lands it would amount to from 25 to 30 per cent of $500,000, roughly stated. If there had been no increase in the value of lands during the period of construction, of course there would not, upon any theory, be any deduction to make on that account.

I made no investigation to determine, and did not determine whether the lands of The Denver Union Water Company increased in value between the time of their acquisition and the end of the period of construction on each item of property.

It is impossible to say with any certainty at all that lands of this description, acquired for the reconstruction of a plant of this sort, would increase in value at all during the next five years. Whether any such increase would occur during the period of construction is entirely speculative.

552 Exhibit 19, Schedule C, cannot state allowances for overhead charges included in gross replacement value shown in column at the left. The notes are destroyed.

The three items of overhead charges which we considered were: First, engineering, considered by itself; second, contractors' profit and contingencies, considered together; third, interest during construction.

In the case of the distributing system the allowance for engineering was ten per cent, and in the case of conduits five per cent. On the other items the allowance for engineering would be greater than five and range as high as ten per cent. Fifteen per cent for contractors' profit, including contingencies, would represent approximately the average allowance.

The percentage of engineering was applied to the cost without the addition of contractors' profit and contingencies. Likewise, contractors' profit was computed on the net cost exclusive of engineering. If I had applied the percentage of engineering to the total cost, including contractors' profit, I would have reduced the percentage. This is the method in that respect which I have pursued in my practice. I do not know whether it accords with the general practice. Frequently work is done—and the largest part of the work done by my construction company is so done—upon a percentage basis, so that the owner knows the actual cost to the contractor. I do not know how general this method is.

As to taxes on the lands during construction, they would amount to a considerable sum. Assuming the period of construction to be five years and the annual taxes $4,500, they would amount to $22,500, which is an actual out-of-pocket cost which must be taken care of in the estimated cost of reconstruction; and that item is intended to be covered by our allowance of development expense.

On the structures, the allowance for contractors' profit varies in the different classes, being fifteen per cent in most cases. The lesser allowances were made in those cases where the cost of materials constituted the greater proportion of the total cost. Where the contractor makes his bid without any guaranteed profit, 15% for the contractors' profit, including use of tools and equipment and contractor's overhead cost, is the usual amount estimated.

In our estimate and in our allowance for contractors' profit and contingencies, the maximum allowance for that item being 15%, we included, in addition to the contractor's profit, the contractor's contingencies only. The company itself may suffer additional costs on account of contingencies. In this instance the company's contingencies would be covered in part by the allowance for engineering.

553 In the 15% allowed for the contractor we did not intend to cover any contingencies or overhead expenses except the contractor's own. The engineering allowance, by which, as stated, the company's contingencies might be covered, went as low as 5% on the conduits. In that case I would not consider that the contingencies were more than those of the contractor.

In the case of Lake Cheesman we did not include in the reproduction of cost of the structure the cost of the original structure which had been washed out. We concluded to allow only that portion of the preliminary investigation which would be necessary in the case of any structure of a similar nature, and that allowance was covered in our

item of development expense. That item, however, did not cover the cost of the original dam, which we concluded not to allow at all.

All of the preliminary expense, the digging of test pits, borings and the like, preliminary to the construction of Lake Cheesman, is covered by the item development expense. The cost of such work must have been large, but I cannot estimate the amount. Our board did not make a separate estimate of that item, but merely concluded that the item of development expense would cover it.

We made no allowance whatever to cover the company's contingencies except as stated above.

In the case of the conduits, the 5% allowance for engineering does not cover any contingencies, and if contingencies are covered at all in the reproduction cost in that particular schedule, they are covered by the contractor's allowance of 15%.

In Exhibit 19, Schedule C, we included nothing whatever for the paving of the Ashland Avenue reservoir. The paving was in bad condition, and we considered that it was performing no office, and therefore was of no value.

I think Exhibit 19, Schedule C, item Tanks and Stand Pipes, is in error as to net value.

Exhibit 19, Schedule C, item Capitol Hill Reservoir, I think the principal difference between our estimate and that of Metcalf and Anderson is in the excavation and embankment. Moreover, our figures do not include a number of miscellaneous items that have some relation to that reservoir, such as the roofing, the piping, the gate house, etc.

Exhibit 19, Schedule C, item West Denver Reservoir, I do not know whether anything included on account of railroad tracks and roads. The paving in that reservoir amounts approximately to 34 cents per square yard, being a total allowance of 5,234 for 12,450 square yards.

It would take some time to determine the allowance for overhead and interest during construction on Schedule C.

554 The witness is requested to refigure these schedules in Exhibit 19 relating to structures, and segregate interest during construction and overhead charges on each schedule.

Exhibit 19, Schedule D, basic figures furnished by Mr. William Allen, as shown by his Exhibit 21, and gross replacement value built up by adding thereto our percentages.

Exhibit 19, Schedule E, also built up by adopting the basic figures of Mr. Allen and adding thereto our percentages.

As to Schedule E, my recollection is that engineering was added at 5% and contractor's profit and contingencies at 15%, making 20%.

As to conduit No. 8, we added nothing to Mr. Allen's figures because of what he had omitted in respect to the East portal of the tunnel.

Mr. Allen's schedule also includes a stand pipe at $4,200, which I think is also included in Schedule C at $4,000, both figures being gross reproduction cost figures. I think this is a duplication.

Exhibit 19, Schedule F, basic figures for the most part furnished

by Mr. Flood. To some of these costs as furnished by Mr. Flood we applied certain percentages.

Exhibit 19, Schedule G, Distribution System, more fully explained in detail by Exhibits 24 and 28. One item of difference between ourselves and Metcalf and Anderson in the distribution system I suppose is the inclusion by them and exclusion by us of the corporation cocks. We estimated the reconstruction of the distribution system in its present location. Cannot give the separate details as to extra allowance on account of street railroad crossings, telephone conduits and other obstructions. Cannot give in amount the extra amount on account of street railroad crossings or on account of steam railroad crossings. River crossings are separately stated.

The corporation cocks included by Metcalf and Anderson and excluded by us are the connections with the mains only, that is, the tapping of the mains and the taps and the connections thereto by which the various service pipes are connected with the mains of the Company.

In many places Water Company mains run along under street car tracks and parallel th-reto. It is my recollection that we took that into consideration.

We included cost on account of paving over mains.

Our unit costs on pipe, delivered at the trenches, are as follows: 2 inch pipe 12 cents per foot; 2½ inch pipe 19 cents per foot; 3 and 4 inch cast iron pipe $32.75 per ton; 6 to 16 inch cast iron pipe $31.75 per ton; 18 inch cast iron pipe, or sizes above, $31.50 per ton.

555 The sheet in our Exhibit 28 showing average costs for 51 cities and cost to The Denver Union Water Company relates only to lead and jute for laying, and does not cover cost of excavation or back-filling, or cost of laying the pipe. The actual cost figures shown by Metcalf's Exhibit A-12, although they relate to work in the outskirts and less thickly settled portions of the city, are higher than the average prices assumed by us. Work in the down-town districts would cost more. Therefore the average actual cost would be greater than those figures show. We had some figures of actual cost at the time of our estimate, but just what they were I do not remember. My judgment is that the figures shown in A-12 represent higher costs than we estimated, because of piece-meal construction, wh-reas we considered it as one continuous replacement, leaving piece-meal construction out of consideration. Piece-meal construction costs more than continuous construction, largely because of the increased overhead expense. The overhead expense I understand is entirely excluded in Exhibit A-12.

In the distribution system we did not assume the use of trenching machines, but assumed hand work throughout.

As to cost of cast iron pipe, we took present day quotations. Cast iron pipe is a commodity which fluctuates considerably in price, but we did not undertake to get the average for any previous number of years. If we had any statement from The Denver Union Water Company as to actual prices paid by them for cast iron pipe, it was not given any weight in our determination.

Exhibit 19, Schedule G, Distribution System, was made up entirely by the board of engineers.

Exhibit 19, Schedule H, Mr. Brown furnished the basic figures. From those we built up the gross replacement value by the addition of certain percentages.

Exhibit 19, Schedule I, was the one estimated by Mr. Flood. The figures are exactly those furnished by Mr. Flood. We applied no percentages. I do not know what percentages ought to be added. I could not even approximate the amount.

Exhibit 19, Schedule K, is the miscellaneous schedule.

The witness' attention is called to certain errors in Exhibit 19, Schedules C, E and K. Also in schedules A and B, Exhibit 23.

Total of Schedule C as written in Exhibit 19 not correctly stated in Exhibit 23.

If the net value of Harriman Lake and Wynetka miscellaneous shown in Schedule C. Exhibit 19, be deducted from the total shown in that Exhibit, the result would be the amount carried forward into Exhibit 23.

556 Exhibit 19, Schedule G, the total does not agree with the amount carried forward and placed in Exhibit 23, Schedule G. I do not know why. There are other corrections to be made.

The item "Development Expense" appearing on page 2 of Exhibit 23, "includes all items which we were not enabled to secure definite information on, including items of preliminary expense in development, various items of overhead charges of various kinds in connection with the system as a whole. In other words, it was something to embrace practically all miscellaneous items that we were not able or did not have the time to get definite or detailed information on." That was our understanding of development expense at the time of the conclusion of our work, but not at the time when we wrote that portion of our report dealing with development expense. In that written report we said on the subject of development expense, in substance (verbatim quotation in original transcript), that a public utility corporation is entitled to a fair return. If it has not earned such fair return, the deficiency, if any, must be included in the price to be paid for the property. "This is perhaps better termed replacement of development expense, and it is to the determination of this amount of deficiency in development expense that we have confined ourselves." To determine this deficiency, value of the property at the beginning of service and at reasonable intervals during life of corporation, as well as rates of interest constituting a fair return for different periods, and average rate of depreciation, and proportion of value of non-depreciable property, such as lands, must be known. Accurate knowledge being inobtainable, the following assumptions were made: First, value in October, 1894, equal to the par value of bonds issued in payment of property, and par value of bonds issued each year thereafter represents fair value of property subsequently added; second, average of 7% per annum is fair average return for entire period; third, 1% per annum on whole value as represented by bonds, including discount on bonds,

lands, etc., would be fair average depreciation on perishable elements.

These statements we immediately followed with a tabulation. Exhibit A-64 is a copy of that table as it appears in our report. We followed this in the report with the following statement, in substance (verbatim quotation in original transcript): In this tabulation interest received on bank balances has been deducted from interest due on bonds issued. "Column 4 is the estimated fair return to which we believe the company to be entitled, based on eight per cent of the par value of the bonds issued, seven per cent of which is directly for a fair return on the investment, and one per cent for depreciation on the par value of the bonds issued.

557 We also stated in that report: "Your committee has duly considered that the interest basis adopted (seven per cent, with one per cent added for depreciation, or a total of eight per cent) represents a fair earning at the present time, but may not represent a fair earning during the earlier periods of the Water Company's operations," by which we meant that during the earlier period of the companys operations it should have been higher.

We also stated in that report, referring to said tabulation, in substance as follows (exact quotation in original transcript): that it serves to illustrate that, even under municipal ownership, "the question of rates, or the material reduction of rates must be approached with caution, in order that the citizens may not be called upon to supply deficiencies in revenue from the water system by taxation."

We also stated in that report, in substance (verbatim quotation in original transcript), that if the return has been less than the fair value of the property should have earned, the company is entitled to the amount of the deficiency; that it may be further contended that there is no provision in the franchise or permit that the earnings of the company shall be limited to a fair return. "We submit the foregoing estimate of the amount of deficiency in revenue as the fair measure of the amount of development expense due to the company at this time."

The amount entered in Exhibit 23 on page 2, opposite the item "Development Expense," is the exact amount stated in our original report quoted from as above, and shown upon the tabulation in said report, copy of which is complainant's Exhibit A-64. Nowhere else in that report do we deal with the question of development expense.

We computed development expense in the manner stated in the report because that is the only way that appeared at the time to be open to us to compute it, and I recognize that a utility corporation is entitled to have a return of this deficiency in revenue.

Personally, I think that development expense, determined in that way, should be included in the rating base. For inclusion in the rating base in a rate suit it should, in my judgment, represent the deficit in revenue, calculated as shown by complainant's Exhibit A-64, for the period during which the company has operated.

We assumed that the property in 1894 was worth the amount of the bonds issued therefor. We did not know what value, if any, attached to the stock which also was given for the property. We also

assumed that no money was invested after 1894 except money realized from additional bonds sales. If there were sums of
558 money applicable to dividends, which instead of being declared in dividends, the stockholders preferred to reinvest in the plant, that is additional capital invested. But if only the sinking fund or depreciation account is so invested, I think that there is no increase in the capital account. That applies to the one per cent allowed for depreciation. If out of moneys accruing under the earnings covered by the seven per cent allowance funds were reinvested in the plant, that is additional capital. If such additional investments were made in the case of The Denver Union Water Company, they should be added to the rating base, although that was not done in our tabulation which is Exhibit A-64.

I do not think the revenue deficits, however, should be added each year. I do not know what the practice of the Wisconsin Railroad Commission in that regard is. Personally I do not think it a proper practice.

In determining a rating base it makes no difference where the capital invested came from, whether out of the pocket of the producer of the public utility, or by the sale of stock in the corporation holding the title thereto, or by the issuance of bonds secured by a mortgage on the property; the actual capital investment remains the same. And if the Supreme Court of the United States has held that the rating base is the present fair value of the property, it makes no difference whether there are outstanding bonds or not, or whether a sinking fund has been provided or not, or whether all or any part of the bonds have been amortized or not.

Never obtained from Water Company a statement of amounts invested out of capital not obtained by the sale of bonds, nor of amounts invested in the plant from earnings.

Our tabulation, a copy of which is complainant's Exhibit A-64, was based upon the theory, which in my judgment is a correct theory, that the public utility is entitled each year to a return at a rate estimated to be fair.

We omitted the addition of yearly deficits to the rating base, and also omitted the addition of investments made otherwise than out of the proceeds of bond sales, because we considered as an offset that the fair value of the property in 1894 was probably less than the $7,000,000 in bonds issued therefor and that the surplus expended for improvements, extensions and additions were proper expenditures for maintaining the property value, in the absence of a sinking fund, and not properly an addition to capital account.

We had no definite information as to the value of the property in 1894. We understood that some of the bonds were issued for stock in underlying companies.—The Denver City Water Com-
559 pany, or The Denver City Water and Irrigation Company, The Domestic Water Company, The Beaver Brook Water Company and The Mountain Water Company. Our assumption that the seven million dollars basis with which we started was probably too large is founded upon such an understanding with respect to issuance of bonds for stock in underlying companies, and if we are

wrong in that then our other assumption is wrong. Until I have other information I still think that seven million dollars is the proper basis to start with.

At least that portion of deficit in net earnings outside of deficit in depreciation allowance should be added to capital account, but I think that would be influenced and reduced by the failure to apply the depreciation account or the increment in the depreciation account to a reduction of the bond issue and the interest charges accordingly. That is the best explanation I can give of my theory regarding my failure to add these deficits from year to year to the rating base. If the property is maintained by the depreciation account, then the remainder would be a proper addition to the capital account.

I think the interest which would accumulate upon the depreciation reserve ought to be offset against the interest upon the deficits in earnings.

Development expense and the amount thereof set down in Exhibit 23, page 2, was determined by the method and upon the principles described above. The various items, such as interest during construction on lands, overhead charges on lands, taxes during construction on lands, preliminary expense of investigation, etc., which I have stated to be covered by this item of development expense, are in my judgment reflected in the deficits in revenue by increasing the operating expenses.

My computation of deficits begins at the time when operations begin.

I do not think I am confusing the question of reconstruction cost and actual cost in allowing this item of development expense to cover actual costs involved in reproduction of the plant.

I regard development expense, determined and considered as a deficit in net earnings, to be a proper item for inclusion in the rating base.

Personally I do not regard going value, or going concern value a proper item for inclusion in such rating base. I distinguish between development expense and going value, or going concern value. I consider going value as synonymous with business worth, and development expense as an element of expense in the development of property and in bringing it to a productive basis. By going
560 concern value, I mean a value arrived at by the capitalization of net income. It would be the relation that the net income bears to the ruling rate of interest. Net income is that which results after deducting from gross income for depreciation, interest charges, operation, maintenance, taxes, insurance, and items of that sort. What I would estimate the going concern value of an enterprise would be the earning value of that enterprise, being said net earnings capitalized at whatever rate of interest I should have to pay to secure the money to invest in the enterprise. That would be limited by the length of time that the operations might continue uninterruptedly.

Therefore, according to my definition, going concern value rests primarily upon the rates which the utility collects, and that is why I think it is not properly to be included in a rate making case.

Going value, or going concern, value, according to my definition of it, is I think a proper element to be included in a determination of value for purchase, and I would so include it as an item separate and distinct from development expense. It is the business worth. The cost of building up a new plant to the situation now occupied by the present plant, would be a definite item of cost in addition to the labor and materials in constructing the plant; that is the cost of building up the business after the plant was ready to operate. I call that development expense, as distinguished from going value or going concern value.

In my judgment, whatever it costs, not only to construct the physical parts of the plant, but also build up the business, is a proper item of cost which ought to be included in the rating base. But any value which arises, either directly or indirectly, from a capitalization of income, or net income arising from an application of current rates, ought not to be so included.

I cannot approximate the amount which I would include here for going value, or going concern value, as distinguished from development expense, if this were a purchase case.

Exhibit 23, Sheet, 3, shows the depreciation applied by us to each class of property. Sheet 4 is explanatory of the deductions made on Sheet 2. The first items for deduction listed on Sheet 4 of Exhibit 23 are the Harriman Lake lands. The last items there listed are the Harriman Lake structures. In view of the difference between the total of Schedule C as it appears on Exhibit 19 and on Exhibit 23, it may be that the Harriman Lake structures are twice deducted. We expect to make up a new set of exhibits and correct these and other errors.

561 We deducted the unirrigated portions of the ranches, but retained the irrigated portions upon the assumption that they were necessary to keep the water rights unimpaired.

If the ranches are excluded, there should also be an exclusion from income and operating expense of the income and operating expense pertaining thereto.

I do not think in making a determination of value of this sort all property ought to be excluded except that which is actually at the moment in use. I would exclude all property which is not in immediate service and that which is not likely to be in service in the reasonably near future. I consider it proper for the Water Company to make reasonable provision for the future, and to include in the valuation of the property for rate purposes the value of property provided for future use, if that use is to occur within the reasonably near future.

We also excluded the pumping units at the West Denver pumping station operated by the water power, including all of the old sections with the exception of the Gaskill units. We did not look into the question of the amount of water pumped in recent years by the power pumps, or the proportion of the total amount pumped at that station which the power pumps actually pumped. We got some information, but it was of a cursory and very general nature. We did seem to realize from the amount of water pumped from that station

that the Gaskill pumps, the steam pumps, either of them was capable at rated capacity of handling all of the water which was pumped from that station. The average yield of the Mississippi Street galleries, as we had it, was 5.3 million gallons, and each of these pumps was rated at a capacity of six million gallons every twenty-four hours.

If water is frequently furnished from that source at the rate of 12 or 13 million gallons daily, the two Gaskill pumping units, if they could reach their rated capacity, would supply 12 million gallons, but that would leave no reserve pumping apparatus.

In water works practice it is considered wise to have reserve pumping units. I consider it unwise to maintain a large reserve for the pumping of water from the Mississippi Street galleries, because that water is more liable to pollution than any other water in the system. Also we considered that there was opportunity for sufficient reserve capacity through the other conduits to supply any short heavy requirement that might occur in the system. If I were the owner of the property I would not entirely eliminate those pumping units from the plant, but if I were a purchaser I
562 would not pay anything but the scrap value for them as an element of property. In this estimate I think we have not allowed even the scrap value.

One element that entered into our judgment was our theory that the Mississippi Street source of supply would sooner or later have to be given up, but our judgment was based principally on the assumption that the pumps were not at that time deemed by us necessary for the service that could be put upon that station. The water from the Mississippi Street source has up to this time remained pure.

We made no determination of the cost of furnishing water from the Mississippi Street source as compared with like water from other sources of supply owned by The Denver Union Water Company. We made no analysis to determine the cost of pumping by the water power pumps as compared with the cost of pumping by the steam pumps. The cost by the water power pumps must be less than by the steam pumps, though how much less I have not the remotest idea.

A reserve pumping capacity equal to the average capacity of the system to yield water is in my judgment all that need be maintained at any one point.

Three pumping units at the Platte Canon works were also excluded. One was included for sand pumping purposes, for cleaning the sand on the slow sand filters. I believe those pumps were installed to pump water from the slow sand filters into one of the conduits, but so far as I have been able to ascertain they have never been used for that purpose. If as a matter of fact those pumps are so connected up that in case of accident they can pump the water directly from the filters into a conduit, I should want to investigate the matter further and renew the consideration that we gave it at that time before being able to say whether or not those pumps ought

to be excluded. I think it is not only proper, but it is necessary, to provide reasonably for all contingencies.

The duplicate pipe excluded is pipe of small sizes, merely left in the ground and apparently not now performing any service.

Exhibit 24, Detail of Distribution System, is to be considered in connection with the larger Exhibit 28, which goes into further detail on the same subject.

Exhibit 25 shows certain deductions from the valuation placed upon this property by Metcalf and Anderson. In said exhibit a number of things are deducted which were not deducted from our own valuation by myself and associates on the committee of engineers. Deduction is also here made of certain items upon which we placed no value at all.

563 In our report to the Public Utilities Commission we stated in substance (exact quotation in original transcript) that we had listed and deducted those elements of property not considered necessary to the system, and also certain elements of obsolescence. We meant by that language that the things which we then deducted were the things which we considered as unnecessary to the water works system.

We also made the statement in that report, which appears on page 1 of Exhibit 23, the latter being a copy of that portion of the report, to the effect that the attached list summarized the value of that part of the property which is an essential part of the water system.

Likewise in that report the statement was made, of which page 2 Exhibit 23 is a copy, that the property summarized is considered necessary to the operation of the water system present and prospective.

Also in that report we made the statement, of which sheet 4 of Exhibit 23 is a copy, referring to the deductions then made and stating that the property so deducted is that "considered as not necessary or essential to the operation of the water system, if purchased by the city, or obsolete."

We then deducted all of the property which at that time we considered not essential. I have not since changed my mind regarding that matter, except as to the Lake Archer canal and lands, which should be excluded if the water power pumps are to be excluded. With that exception my opinion is now the same as at the time when the said report was made.

The question whether the ranch lands should be included or excluded depends upon the solution of the legal question as to whether their retention is or is not necessary for the proper maintenance of the water rights.

Exhibit 25, page 1, item 1, is based upon the assumption that some value should be included for water rights, the value there given being $565,980. At the present time I have no personal judgment as to the value of the water rights. Therefore this first item of deduction does not represent my personal judgment at all. It is a mere matter of computation, as before explained. As to that item, I merely answer for the correctness of the arithmetical computation. The detail of that computation is given in Exhibit 26.

Exhibit 26, page 1, column 1, based on figures in Exhibit C, converted from million gallons into second feet; column 2, headed "Holman," based on a letter introduced during Mr. Holman's testimony, the letter having been written in 1908, and setting forth Mr. Holman's personal determinations as of that date. Since
564 that date there have been some important changes in respect to the water rights.

Exhibit 26, page 1, column 3, "Capacities of System", more fully explained on page 2 of Exhibit 26. Exhibit 26, page 2, states the capacity of the conduits which convey the filtered water, and thereby we are limiting the capacity of the system by the capacity of the principal clear water conduits, to which we add the water for ranch purposes.

As to the 3.92 second feet for ranch purposes, that is arrived at by the method shown on last page of Exhibit 26.

Discussion of third page of Exhibit 26. Defendants' counsel withdraw from consideration column on that page headed "Water Rights as Deducted."

Exhibit 26, page 1, column 3, "Capacities of System", really represents actual average drafts on the infiltration and filtration systems, not the capacity of the conduits to convey.

Exhibit 26, page 1, column 4, "Average Daily Consumption, Maximum Year," is explained by table appearing at bottom of page 2 of Exhibit 26. The figure taken is the average daily consumption for the year 1910, although there are days in the year when the rate of consumption is very much greater than the average, and there are times in the day when the rate of consumption is greater than the maximum daily rate. At times of peak demand, which occur during irrigation hours in the summer time, water must be flowing from the system at a rate greater than the average for the day. There must be a supplemental supply capable of providing the actual daily use of water, and water rights must be provided capable of furnishing that kind of a supply.

This table is predicated upon the theory that the Water Company has no right to take a single drop of water in excess of that which it took in the year 1910, plus the use which it made of water to irrigate its ranches, and plus the evaporation from the reservoir surfaces. I would not undertake to say that as a matter of law such a theory is sound. No part of this table is a matter of my interpretation of the law. It is simply given for purposes of comparison.

The quantity taken to which the unit price of $6,000 per second foot was applied, as appears on page 1 of Exhibit 25, was the smallest quantity arrived at by any of my computations.

A flow at the rate of 94.33 cubic feet per second is the direct constant flow needed to supply the actual consumption, and furnishes nothing to fill the company's reservoirs, which have an aggregate capacity of approximately 100,000 acre feet. It is necessary
565 to have the reservoirs to furnish a supplemental or reserve supply.

The $6,000 per second foot, said to be from a statement of George G. Anderson, was from a statement made in 1908, and applicable to

the Platte Canon Ditch as it was then conditioned, and possibly to the summer flow thereof only. As to that I do not know.

The quantity of water furnished by a second foot right depends upon the length of time that the flow continues at that rate. Its value for irrigation purposes depends upon the time of the year when the water is available. So that a second foot right varies in value with respect to the ditch in which the right exists, the appropriation of the ditch, the probability of the ditch being able to get its appropriation in full or in part, and the times when it does get it. A second foot right in the English High Line would be worth very much less than a second foot right in the Platte Canon, although their intakes are quite close together.

A second foot right in the Platte Canon ditch for irrigation purposes, considered simply as a direct flow right, so that the water is usable only in the irrigation season, would produce a much less volume of water and be of less value than a second foot right in the Platte Canon Ditch with an all year round flow and a proper storage reservoir to store the flow, so that the entire volume of water so produced could be made available during the irrigation season, and in the critical period of the irrigation season, or at the time when water is most needed for irrigation purposes.

In the foregoing particulars there has been a marked change in the Platte Canon Ditch since 1908, in that by conduit No. 7 a connection with Marston Lake has been made and storage thus provided.

I do not mean to say that in my judgment $6,000 per second foot is the value of these water rights. I do not answer for the correctness of that assertion. Nor do I state it as my judgment that 94.33 second feet is the total quantity of water owned by The Denver Union Water Company, and which ought to be included in the rating base. That also is a mere assumption.

It is proper in my judgment to include in the rating base additional property provided for growth within the reasonably near future, and there should be an added element of quantity on that account in respect to the water. That is not included in Exhibits 25 and 26.

94.33 second feet flow for a year would produce 67,000 acre feet, which at the value assigned in Exhibit 26 would be $8.50
566 per acre foot, which seems somewhat low. In Exhibit 26, page 1, the second feet listed at the bottom of column 1 would produce 135,130 acre feet, which is more than the total quantity valued by Mr. George Anderson and included in his estimate, that quantity being approximately 107,000 acre feet.

Exhibit 25, page 1, item 2, going concern value as estimated by Mr. Metcalf excluded upon the theory that it is going concern value according to my definition thereof, and not development expense as defined by me. If I am wrong in this, and it represents development expense, I think it is excessive. If as a matter of fact it represents development expense as defined by me, it ought not to be excluded, except that part of it, if any, which represents an excessive allowance. The item should not be entirely excluded unless develop-

ment expense has been elsewhere included in their valuations. If Metcalf and Anderson have added nothing which is included in the valuation of physical items on account of development expense, then a separate item covering that element of value should be included in the total.

Exhibit 25, page 1, item 3, is more fully explained on sheet 2 of said exhibit.

We deducted Sullivan reservoir, both lands and structures. It is not at present used as part of the plant, although it might be so used. It would be good practice on the part of the company to make use of it in connection with an enlargement of the plant. In our report to the Public Utilities Commission we considered the use of the Sullivan reservoir in connection with storage and the operation of the system by gravity. We had in view the use of the Sullivan reservoir as one of the reservoir units for that purpose, and spoke of plans made by The Denver Union Water Company and conduit lines surveyed, which would so utilize the reservoir. We regarded those plans as feasible, and as plans to be recommended to one owning the Sullivan reservoir and the rest of the Water Company's plant.

In our report we also gave consideration to plans for utilizing Sullivan reservoir by the construction of additional galleries on Cherry Creek. These plans also would be feasible. Under those conditions I do not know whether Sullivan reservoir as it exists is a desirable part of the plant, to take care of future changes which we estimate will be necessary in the reasonably near future. The reservoir has, of course, a great deal of money expended on it, but it will require a great deal of improvement to make it available in any system. However, it is my opinion that in a rate making case it can properly be excluded.

567 As to the exclusion of the water power pumps at West Denver, the rated capacity of the two remaining steam pumps would be approximately 12 million gallons daily. Although water is pumped and furnished from that source frequently at the rate of 12 or 13 million gallons daily, nevertheless, according to my idea, that would be a sufficient provision of pumping capacity. Even though less than the peak load capacity, I think that with the other sources of supply that is a sufficient provision. But if one of the steam pumps broke down it would not be possible to pump the peak load from that station. Nevertheless I should consider that it was well up to the average in having capacity to supply the peak load for short periods, and a capacity largely in excess of the average furnished from that station. Not aware that the average in 1910 was 10 million gallons per day, and in the month of June 15 million gallons a day. Not aware that in June and July, 1913, the average daily withdrawal from that station was 15 million gallons, the same thing being true in 1912 and in 1911, in those months. Notwithstanding those facts, we do not think that any supplemental pumping capacity should be supplied at that station.

Exhibit 25, page 5, item 20-A was included in our own valua-

tion, or rather was not excluded from it. If we had had more time we would probably have excluded it.

We did not intend to exclude all of the lots on Cottage Hill. If that has been done here, the exhibit should be corrected.

Item No. 27, page 5 of Exhibit 25, Lake Archer canal and conduit lands, covers all of such lands, and excludes the entire value thereof as shown in Exhibit C. The galleries themselves are in any event to be retained, as well as a right of way for the conduit. Lake Archer and its canal are excluded upon the theory that the water power pumps at the West Denver station are to be excluded. I consider the exclusion as made here erroneous, even upon that theory, inasmuch as it excludes also the galleries and the conduit right of way.

As to the exclusion of all of the ranch lands, that portion of the same occupied by the conduits ought not to be excluded. The exclusion of the remainder is based upon the theory that they are unnecessary to the proper maintenance of the water rights. If it is necessary or advisable to retain them for the protection of the water rights, they ought not to be excluded. Even if the law be doubtful on that point, it would be prudent to retain them. If excluded, the income and operating expense and taxes pertaining thereto should also be excluded.

Exhibit 25, page 1, item 4 is explained in detail on page 6 of Exhibit 25. It merely represents a difference between the net reconstruction cost of the distribution system as estimated by Met-
568 calf and Anderson and by ourselves, the difference being here deducted.

Exhibit 25, page 1, item 5 is explained on page 7 of Exhibit 25. It merely represents the difference in the valuation of all the schedules, with the exception of the valuation of lands and the distributing system, which are separately considered, between the valuations of Metcalf and Anderson and those of our committee.

Our item of "Development Expense" was intended to include, among other things, the item designated in Exhibit C, page 64, "Preliminary expense and organization $120,000."

The deduction of item 5, page 1, Exhibit 25, taken in connection with the other deductions previously made, brings the valuation of the physical elements as found by Metcalf and Anderson down to the level of the valuation of the Utilities Commission.

Exhibit 25, page 1, item 6, the effect of that item is to assume as the valuation of the Lake Cheesman lands their assessed value for purposes of taxation, to-wit, $114,120. That assumption is not in accord with my judgment. We obtained the assessed valuation from the records of the counties, to the best of our ability.

Exhibit 25, page 1, item 7, calculation based upon annual depreciation at rate of $138,000, from which is deducted new construction or betterments during the period.

Exhibit 25, page 1, item 8, paving over mains. The amount here deducted was included in our own valuation, and still is. In my judgment it should be so included. Its deduction here does not

reflect my personal judgment. It was deducted at the request of the attorneys for the defendants.

Exhibit No. 27 represents certain computations made at the request of counsel, and upon assumptions the general outlines of which were prescribed by counsel in each instance. In that exhibit depreciation for the year 1913 does not include the contingent reserve testified to by Mr. Metcalf. That contingent reserve item of thirty or forty thousand dollars per annum is not included anywhere in Exhibit 27.

Percentage of net income upon a valuation of sixteen million dollars should be 3.053, instead of 3.53. It should be corrected.

Depreciation allowance for the year 1914 not taken from Mr. Metcalf's exhibit.

Gross revenue for 1914 was taken from Mr. Metcalf's Exhibit A-25. I did not consider the testimony as to what the actual gross revenue for 1914 has been.

I have assumed the same depreciation allowance throughout, to-wit $138,000, although various witnesses have testified to
569 higher rates, and although Mr. Metcalf testified that the depreciation allowance ought to be about ten per cent of the gross revenue.

In Exhibit 27 it was assumed that for the period 1914 to 1919 there would be no additions to capital account.

Gross earnings are taken from the forecast in Exhibit C, based on Metcalf's population curve. So far the population has not increased as estimated.

I have excluded the extra legal expense in 1914, but in my judgment the cost of the rate reduction case ought not to be so excluded.

Exhibit 27, sheet 4, revenue deficit table, explained. The tabulation is for comparison with Exhibit A-19, table 2, using six per cent instead of seven per cent as the fair return. The result shows the unreliability of this method of determining development expense when applied to a long period of years.

I am still of the opinion, as stated in our report to the Public Utilities Commission, that seven per cent, with one per cent added for depreciation, or a total of eight per cent, represents a fair earning at the present time, although in the earlier life of The Denver Union Water Company the rate of return ought to have been greater; and in my judgment that rate of return ought to be applied to the present fair value of the property. There is a difference between a reasonable rate of return and the cost of money fixed by the going rate of interest. One who furnishes a public utility service is entitled to something upon the present day value of his property in addition to the going rate of interest. The going rate of interest is one of the costs of furnishing the service, to-wit, the cost of money. In addition to that, the public utility should have something by way of profit, to cover the hazard of the business and things of that character. If the cost of money to a public utility is six per cent per annum, then something in addition must be added to make up the reasonable rate of return. What we start with is the cost of money to the particular utility, and to that rate per cent

must be added some additional percentage to cover the profit item, the latter depending upon the risks involved and other considerations going to affect the profit which the operator of the utility should get.

The cost of establishing the business, as distinguished from cost attached to construction of physical parts of the plant, should certainly be included in the rating base as part of the investment, unless it has already been amortized by reason of realization of more than a reasonable return. In that respect I distinguish between amortization of cost of building up the business and cost of physical parts of the plant.

570 Exhibit 27, sheet 5, "Revenue Interest Paid and Profits." Column headed "Interest" compiled from statements obtained by me from Water Company. Accrued depreciation deducted at foot of last column does not include abandoned property. I attach no special significance to this table.

Exhibit 27, sheet six, last table, represents profit on taps, with interest thereon to the present day at the rate of four per cent per annum, compounded annually. Do not know whether the company ever received such increment thereon.

The engineers of the Public Utilities Commission were engaged upon their work from some time early in August until about the middle of January following. We made repeated and careful inspections of the physical parts of the plant, as much as we could within the period. We caused the conduits to be exposed in a large number of different places, the places being designated by us, and we particularly designated the length of the trench, the dimensions of it, etc.; the openings to be six feet in length, so made as to expose the pipe for its entire circumference, and directed that three feet of that length be left without the earth cleaned off, and the remaining three feet the earth to be washed off the conduit. Those openings were made in the manner and at the points directed by us. We designated about seventy points to be so opened, and examined probably forty. These were distributed over the several conduits, the older as well as the newer conduits.

As the result of those investigations and inspections, we assigned to the conduits an estimated life, to which I have testified, and determined the accrued depreciation thereon, which our exhibits show. In our report to the Public Utilities Commission we referred to these examinations and their result, and concluded: "From these examinations we consider the assumed average life hereinbefore stated as conservative, under local soil, pressure and operating conditions." The assumed average life of the wood-stave conduits there referred to and as designated by us was 40 years. We meant by the expression that the actual average life of the conduits was at least 40 years in our judgment. We made a like inspection of other parts of the plant.

We also investigated the question of pressure and the question of service being performed by the plant, and our conclusions in that regard are set forth in our written report to the Public Utilities Commission.

We were hurried in our work by the Public Utilities Commission, or its members.

The exhibits presented by me are to be revised, recalculated and checked up.

571 I have had access to plaintiff's Exhibit C ever since it was introduced, but I have not checked up the estimates therein contained, nor critically examined the exhibit, nor analyzed the values or the computations or the bases of values as set forth in that exhibit.

Exhibit A-64, development expense tabulation from report of public utilties engineers, admitted as part of cross examination.

Recalled.

Direct examination:

Exhibit 54 sets forth Exhibits 19 and 25 as revised and corrected, and also some additional matters.

As to Exhibit 19, the paging is the same as in the original exhibit. A sheet, 6-A, has been added, showing the differences between the original and the present Exhibit 19, and sheet 15 has been added, showing engineering, contractor's profit and interest during construction.

As to Exhibit 25, contained in Exhibit 54, the paging is the same now as in the original Exhibit 25, except that there are certain added pages, to-wit, pages 8, 9 and 10.

In the revision of Exhibit 19 all of the original figures in the engineers' report have been checked over, computations carried out and additions made. The figures appearing in revised Exhibit 19, embraced in Exhibit 54, are the completed and corrected figures.

Sheet 6-A shows the difference in figures between original Exhibit 19 and revised Exhibit 19. The deductions made on sheet 6-A are the same as those made in Exhibit 23. The figures, however, have been corrected in the new exhibit. The difference I think is altogether in the item of land value.

Exhibit 54-19, sheet 7 and following sheets explained.

Sheet 10, Schedule F, the principal difference from the original exhibit is the item of West Side pumping station and equipment, in which the pumps in the original schedule were duplicated, causing an error of approximately $66,000.

Exhibit 54-19, sheets 11 to 14 explained.

Exhibit 54-19, sheet 15 shows, so far as it is possible to do so, in totals, the items of engineering, contractor's profit and interest during construction, included in the total. No interest during construction was included on account of Schedules A and B, being the land schedules. So far as the matter was considered by our committee, there was some difference in regard to it, and if there was to be any inclusion for that item, it was to be included under the general item of development expense. The idea was held that the increment in value of those lands covered the items of engineering and interest during construction. The matter was only briefly

572

gone into, and it was allowed to go, if it should be included, in the item of development expense.

Exhibit 54-25, page 1, items 1 and 2, same as original exhibit; items 3, 4 and 5 changed to correspond with changes in corrected Exhibit 19. Item 6 of original exhibit has been omitted, and difference in land valuations included under item 8, page 1 of new exhibit. Item 3 shown in detail on page 2.

Exhibit 54-25, page 2, Schedule A, item 2, shown in detail on page 3, Schedule A-1. Item 3 shown in detail on page 4, Schedule A-2.

As to Platte Canon pumps, from all information we could obtain they had never been used, unless it might be that one of them had been alternated with No. 4 for use as a sand pump. That I could not be certain of at all, but they had never been used for general pumping into the system. This was one of the eliminations from our original valuation.

As to the exclusions at the West Denver station, this includes the exclusion of Lake Archer and Lake Archer canal, also the older portions of the pumping station, with its water turbines and all the water power equipment.

Exhibit 54-25, page 2, Schedule A, item 6, shown in detail on succeeding page 5, Schedule A-3. This differs in several respects from page 5 of original Exhibit 25.

All of these items were not excluded by us in our original report to the Public Utilities Commission.

This tabulation (Exhibit 54-25, page 2, Schedule A, item 6, and page 5, Schedule A-3) does not represent the determination of the committee. It was prepared at the request and suggstion of counsel for the purposes of this case. It covers items for deduction not deducted in our original report.

Exhibit 54-25, page 6, Schedule B, explained.

54-25, page 7, explained.

The final item of net difference is the item shown as item 5 on page 1 of Exhibit 54-25.

54-25, page 8, Schedule D, shown in further detail on page 9, explained. The final figure on page 8 is item 8 on page 1 of Exhibit 54-25.

Exhibit 54-25, page 10 (marked Exhibit 25-54) explained. It is a comparative table, showing comparison between estimates of the public utilities engineers and of Metcalf and Anderson, the latter as shown by plaintiff's Exhibit A-22, exclusive of water rights and of going concern value. It also shows the comparison according to the figures in Exhibit C. The two valuations, to-wit, that of Metcalf and Anderson and that of the public utilities engineers, were
573 not made up in exactly the same way, and it is very difficult to co-ordinate them.

On the Capitol Hill reservoirs, the total excavation figured by us was 79,900 cubic yards, at 16 cents, and 41,860 cubic yards of embankment at 19 cents. To this contractor's profit should be added. At the West Denver reservoir 11,000 cubic yards at 20 cents, to which contractor's profit at 15% should be added.

We have endeavored by Exhibit 54 to correct said errors in former exhibits.

Recross-examination:

The net result of the corrections made by Exhibit 54 is to decrease our total by over $161,000. Practically all of this accounted for by clerical errors in the former exhibits.

Exhibit 54-19, sheet 2, Schedule A, item 26, valuation omitted in former exhibit; present valuation determined by the committee.

I do not know whether any member of the committee has knowledge of values in the vicinity of Morrison. Personally I do not assume to be versed in such values.

54-19, sheet 7, Schedule C, "Structures." A very considerable reduction has been made in the new exhibit, applying to almost every item. This was necessary by reason of errors in calculation originally occurring. The original errors were in the original item of replacement cost before the application of overhead. They were not errors in quantities nor in applying the wrong unit price, but in multiplication and addition.

The difference in Cheesman reservoir is accounted for by a double inclusion of contractor's profit on the item of masonry, amounting to $62,668.

On Cheesman reservoir we allowed no contractor's profit on the cement. The sum allowed for cement was $278,050. The engineering percentage was applied to the cement allowance. I think a contractor would be satisfied with a profit of 15% on a basic figure arrived at by excluding the item of cement.

I am not able to explain the difference on the item Marston Lake reservoir between Schedule C of original Exhibit 19 and Schedule C of Exhibit 54-19.

Exhibit 54-19, sheets 8 and 9, Schedules D and E, explained.

54-19, page 10, Schedule F. Difference between original Exhibit 19 and this accounted for by duplication in original exhibit of pumping units.

Exhibit 54-19, page 11, Schedule G, explained.

574 Exhibit 54-19, page 12, Schedule H, explained. In the original schedule engineering had been omitted.

Exhibit 54-19, page 13, Schedule I, same as original exhibit. No addition made on account of any overhead costs or expenses whatever, notwithstanding Mr. Flood's testimony. This because Mr. Allen stated that there was a great deal of stock carried over for some time, and we regarded that as a sufficient offset, without making any actual determination.

Exhibit 54-19, page 14, Schedule K, explained. Do not think overhead should be added on first seven or on the twelfth item, because I think the figure of replacement cost given is sufficient to include those items. Our committee did not value all of those items, Mr. Flood valued some of them.

Exhibit 54-19, page (or sheet) 15. As to interest during construction and overhead charges on the lands, my view is that original cost plus actual interest during construction and overhead should be

taken, and from this the appreciated value of the lands deducted. It was impossible to make that computation, therefore we considered that the general allowance of development expense might cover any such difference. Our theory was that appreciation in value of the lands ought to be offset against interest during construction, engineering and other like overhead charges; also that those items, including taxes during construction, are items to be applied only to the original cost of the lands, and not to their present day value.

As to interest during construction on the structures, covered by Schedules C to H inclusive and Schedule K, the basic rate used was six per cent per annum. My former testimony to the contrary was a mistake. I formerly stated that the net amount arrived at by deducting interest on bank balances was four per cent per annum. That was incorrect, except as to the distribution system, and even in that case, while it was applied for half of a period of 4.2 years, it would be equivalent to interest at six per cent on half of a construction period of 2.8 years, which is practically three years. As to all other schedules, a net rate of six per cent per annum is used, without any deductions. As to Lake Cheesman, we applied a rate of six per cent per annum, and assumed a construction period of about 2½ years; or about 2⅔ years I think. It actually took longer than that to construct Lake Cheeseman, but I do not believe that the work was prosecuted with all the vigor that would be used if it were carried out as part of the complete system.

We assumed that the entire water works system was to be reproduced. Under such conditions, the constructor would have to have a very considerable part of the total amount needed for construction on hand at the time of commencement of work on the
575 system. We have dealt with each separate element of the system as though each, such as the distribution system, Lake Cheesman, the conduits and each of the other elements, was going to be financed and constructed as a separate proposition.

We have dealt with the elements as nearly as possible in the order of their construction. For example, Lake Cheesman would be begun during the second, possibly during the third, year of the period of construction of the entire system. We assumed that the money was not all advanced and in hand at the beginning of the construction period of the system, but was made available as construction progressed. We made no specific assumption as to how much would be in hand at the time of the beginning of the construction period. We assumed that as to each of the separate elements of he plant interest during construction began to run at the time when the work of construction on that particular part of the plant began. Our assumption was that the builder would not have in hand a substantial part of the total cost at the beginning of the construction, but would have financial arrangements made to get his capital in relatively small amounts, perhaps at six months, nine months or yearly intervals. I think it is quite usual to have an enterprise of that sort financed in that way. Under those conditions the builder would never have on hand or in bank any particular large sum of money.

Some plan of underwriting the bonds by a syndicate is what I have in mind. Such a syndicate I presume would require compensation. If such a banking syndicate required compensation for such an arrangement, that would be a part of the cost of getting the money. In some instances in my experience the banking syndicate has received its compensation in stock of the company, that is to say, in the speculative end of the enterprise.

I have never been connected with an underwriting of such a character and involving such amounts as would be necessary to reproduce this water works plant.

Under the method assumed, there would not be any considerable return by way of interest on bank balances; not nearly so great as if the owner-builder had supplied himself at the beginning of his enterprise with a considerable amount of the cash required.

We assumed approximately four years as the entire period of construction, and that the Marston Lake filter, for instance, would be built in the last year. Practically all of the structures in Schedule C, except Lake Cheesman, would be built in the last year of the four. For Lake Cheesman we estimated a period of
576 construction of $2\frac{3}{4}$ years, construction to begin during the second year of the four year period.

For the entire system I estimated one year for surveys, specifications and plans, and actual construction to begin during the second year. I did not assume that all of the items of the plant would become active component parts thereof at the same time.

I did not assume that work would be carried on so that interest during construction would cease at the same time on all parts of the plant. I did assume that certain portions of the plant would be in service before the end of the four year period. I cannot state what parts of the plant were so assumed.

Interest during construction must continue as to any particular component part of the plant until it becomes an active element. I cannot state what my assumptions were as to the time when any of the elements of the plant would become active.

I do not remember in what year of the construction period of four years the conduits would have been built. The conduits and the infiltration galleries would probably have been completed at about the same time. I cannot state what my assumptions were in that regard. I imagine the conduits would be completed before Lake Cheesman. In our theoretical reconstruction an approximate estimate was made as to when these various structures would be completed; but I am totally unable to state now what that was, even approximately, and cannot say who could.

We assumed that the conduits would probably come into service successively. I cannot state what the assumption was in that regard, but in all probability some of them would be in service prior to the completion of the whole plant, and others would come into service during the latter part of the period of construction. A portion of the system would be in service probably considerably before the four year period expired. I could not say how much before. In making up our estimate we made up a general schedule

on that subject, but not a definite one, because that would involve the development of an entire plan of construction, which was not done.

We dealt with the matter of interest during construction as to each element by itself. On Schedule G, the distribution system, the aggregate percentage of interest during construction was 8.1%. The detail of that is explained in Exhibit 24. We started with a basic rate of six per cent per annum and deducted two per cent for interest on bank balances, giving a net rate per annum of four per cent, which we applied to a period of 2.1 years. If we had applied the same method regarding interest during construction to Schedule G as we did to the other schedules, and figured it at the rate
577 of six per cent for that period, the amount would have been increased by $178,716.

The distribution system was not the first of the component parts of the plant upon which we figured interest during construction, but after that schedule was completed we thought too much time had been allowed, and we thought the overestimate of time offset the underestimate of annual rate of interest, so, being hurried, we left it as it was. Otherwise we would have made the period of construction for the distribution system somewhat shorter and stated the interest rate definitely.

My recollection is not entirely clear, but it is that this was the first item upon which we figured interest during construction. If I just made a statement to the contrary, it was inadvertently made.

If we had shortened the period and increased the rate to six per cent, we would have taken a total period of 2.8 years and would have computed interest at the rate of six per cent per annum for half of that period.

Construction work on the distribution system would commence very shortly after the plans were completed, and it would be one of the last to be completed, although some portions of it would be in service before the completion of the system.

If we had applied the rate of six per cent per annum to the average period of 1.4 years we would have made no deduction for interest on bank balances.

As to Schedule H, buildings, our assumption was that they would be completed from time to time throughout the period of construction. We assumed a period of construction for each building of one year; interest at annual rate of six per cent, with no deduction for interest on bank balances.

Schedule K, assumed a rate of six per cent per annum, with no deduction for interest on bank balances.

As to all of these schedules, except Schedules A, B and I, where no allowance was made for interest during construction, the allowance in every case, except as to the distribution system, was based upon a rate per cent per annum of six per cent, without any deduction for interest on bank balances; but as to the distribution system, Schedule G, we assumed a rate of six per cent per annum and reduced it by two per cent because of supposed interest on

bank balances, leaving a net rate per cent per annum of four per cent.

The statements now made in testimony relative to interest during construction and methods of its calculation are inconsistent with statements contained in our report to the Public Utilities Commission (quoted in full in original transcript). Those sections of the report were written before most of these calculations were made, and were not subsequently changed.

578 My present statements are inconsistent in this regard with the testimony given by me when formerly upon the stand (quoted in full in original transcript), but my former testimony was wrong in that regard, except in the case of Schedule G. All of the testimony which I then gave repeatedly, both on direct examination and on cross examination, when on the stand before, in that regard was erroneous, except as to Schedule G. As a matter of fact, we did not then, and do not now, make any deduction on account of interest on bank balances except in respect to Schedule G.

As stated yesterday, the amount of interest during construction on the distribution system would be the same whether calculated on the basis of an average period of 2.1 years at four per cent, or 1.4 years at six per cent; and if the shorter period were assumed, there was no deduction for interest on bank balances.

When formerly upon the stand I stated repeatedly that I was unable to answer questions because detailed data had been destroyed. Since then I have discovered that one of my assistants, who made most of the computations, definitely remembered what was done and had memoranda thereof, and with his assistance I made the computations.

Exhibit 54-25 explained.

It follows as the natural inference from what I have said that at the present moment I am unwilling to say that in my judgment the amount stated as the final result after making deductions, as the same appears on page 1 of Exhibit 54-25, is the fair, just and proper result.

Exhibit 54-25, page 5, Schedule A-3, item 27. The difference between that item and the corresponding item appearing in original Exhibit 25 arises from the fact that we now permit the company to retain in its valuation the Mississippi gallery lands and the conduit right of way. These are valued at the rate specified in Schedule G; at about an average rate of $1,500 per acre. I have not taken into consideration the added cost of obtaining a mere right of way through these lands, instead of obtaining the lands in the large parcels in which they are held, as testified about by Mr. Armour Anderson and other witnesses.

The net result of Exhibit 54-25 is simply this: That first we deducted from Metcalf and Anderson's valuations certain specific items, then we deducted from Metcalf and Anderson's valuations their excess over our valuations, as to all of the other items in all of the schedules, and so arrived at the result shown on Exhibit 25. It simply amounts to an assumption that according to our view, or according to counsel's view, or according to some possible construction of law which may

be applied by the Master, certain things which have been val-
579 ued ought not to be valued and included in the rating base, and therefore are to be deducted; and that as to the remainder, any difference in valuation which may exist between that found by Mr. Metcalf and Mr. Anderson and that found by ourselves, as to the remaining property, ought to be deducted from Metcalf and Anderson's valuation.

Item No. 6 appearing on page 1 of original Exhibit 25 has been entirely eliminated. As the deduction is now made on account of Lake Cheesman, the amount deducted is the difference between our valuation on Lake Cheesman lands and that of Metcalf and Anderson, so that in the new Exhibit 25 we have deducted about twice as much as in the former exhibit on account of Lake Cheesman lands. I am not now able to state just why I used the other method before.

Exh-bit 54-25, page 1, item 8, did not appear in former Exhibit 25. By reason of this new item we are now deducting an additional amount of $80,000 on account of Lake Cheesman lands, and an additional amount on account of other lands of approximately $80,000, which we did not deduct at all in our former exhibit. The additional deduction here made is approximately $150,000.

Exhibit 54-25, page 8, Schedule D, "Water right values included" by public utilities engineers. Details shown in part by following page 9, which covers approximately one-half of the total.

$60 per acre was our standard valuation for first class water rights. Exhibit 54-25, page 8, Schedule D, further explained.

If Mr. Wall and Mr. Bowles have testified that they did not twice value the Woodbury tract, otherwise designated as Tract No. 15, Arapahoe, then there is no occasion for the note relating thereto in Exhibit 54-25, page 10, at the foot of the page.

Exhibit 54-19, sheet 7, Schedule C, items Capitol Hill Reservoir and Capitol Hill Reservoir Lining do not cover all the estimated reconstruction cost of all parts of the Capitol Hill reservoirs. I think these cover the excavation, embankment and concrete lining only. They do not cover the roofing, outlet, pumps, packing and things of that kind.

It would be possible, but somewhat difficult, to furnish an itemized statement of our estimated cost of reproduction, gross and net, of all the items that go to make up the Capitol Hill reservoirs, and I will make up that statement and present it to you if Mr. Nye so instructs.

Probably the difference in our respective valuations largely arises through the difference in amount of excavation. These quantities
were figured by Mr. C. P. Allen for the committee. We
580 assumed that all of the material excavated went into the embankment. If this is not so, there should be an allowance for hauling away the waste material.

Redirect examination:

"Q. Upon what basis did you consider the construction of the plant, in respect to whether or not it was to be now constructed with

the streets encumbered with pipes as they are, or whether it was to be constructed without such encumbrances?

A. Our final determination was that it was to be considered as if nothing existed—no obstruction existed."

"Q. It was upon that basis that you made your calculation?

A. Yes sir."

The total amount of interest during construction as allowed by us represents six per cent upon two and a half million dollars for each of the four years, or ten millions for one year, or half of that amount for two years.

Recross-examination:

If there was a construction cost in each of the four years of the construction period of two and a half million dollars, then we have computed interest on each of these instalments of two and a half million dollars at six per cent for one year. As to interest on the first two and a half million dollars for the following three years, on the second two and a half million dollars for the following two years, and on the third two and a half million dollars for the following one year, it would be assumed that one-fourth of the plant would be in action at the end of the first year, one-half at the end of the second year, three-fourths in three years, and the remainder in the fourth, and earning a revenue. We did not enter into the question as to whether the revenue would be sufficient to offset the interest on the amount which had been invested, and I would not be able to state whether it would or not.

JOHN E. FIELD.

Direct examination:

State Engineer since 1913. Formerly State Engineer in 1897 and 1898. Civil engineer. Graduate Sheffield Scientific School of Yale in 1888. Practiced continually since in Colorado and the West. For past twenty years almost exclusively in irrigation and hydraulics, in work connected with water rights, appropriation of waters and
581 their use in irrigation. Member Field, Fellows and Hinderlider, Engineering Company, of which A. Lincoln Fellows is also a member.

1902 to 1907 engineer of United States Reclamation Service, in charge of work in Southern Wyoming and Nebraska. Investigations for North Platte project under my direction. Also construction work in connection with Pathfinder reservoir, up to foundations, tunnels and outlets. Expenditures about $3,500,000. After that private practice in Denver, service extending into Wyoming, Utah, Arizona, Texas and Nebraska. Investigation, passing upon feasibility of projects, estimating value of lands and water rights, etc. Where projects constructed often acted as construction engineer. First one during that period in San Luis Valley, covering about 34,000 acres. On Western Slope project near Rifle, covering 10,000 acres, canal about 30 miles long.

In connection with irrigation matters, on South Platte. Some work

on Henrylyn. Also consulting engineer on several projects, especially when they got into trouble.

I think I have considered the flow of the South Platte and all of its tributaries. Quite thorough investigation of flow and use and duty of water on Laramie River. Have examined and considered the flow in various other streams.

Some experience in reservoir designing and construction. Made first plans for Pathfinder dam, which were afterwards altered very little. That is a stream-bed dam, constructed of masonry. Capacity in Pathfinder a little over a million acre feet.

As to administration of water supply for irrigation purposes in Colorado, State Engineer at head. Distribution according to courts' decrees. Immediately below State Engineer are five division engineers, one to each main water shed. Under each division engineer are the water commissioners, each having charge of a section of the main stream or one of the tributaries. Water commissioners have deputies. Whenever shortage of water, division engineer must determine and regulate between various districts.

On South Platte River, beginning at the head, District 23, in South Park; below that District 8, from mouth of canon to Denver; below that District 2, from Denver to mouth of Cache la Poudre; below that District 1, and beyond that District 64.

As between these districts, for example, if a junior ditch in an upper district is drawing water and a senior ditch in a lower district needs it and cannot get it, the junior ditch must be shut down. Moreover, ditches on the tributary streams must always be considered, and a junior ditch on a tributary not permitted to receive water
582 when a senior ditch on the main stream below is needing it. That is principal duty of division engineer. He also hears complaints of injustices or discriminations practiced by the water commissioners. State Engineer gives directions to division engineers, and complaints concerning water commissioners or division engineers are brought to him.

State Engineer also has under him a number of hydrographers, who measure the streams, rate the ditches, and furnish data and information upon which distribution of water is made. This is transmitted to the division engineers and also to the water commissioners.

State engineer also supervises construction of dams over ten feet in height*b*. Also limits the amount of water which may be stored in a reservoir by reason of possible weakness of structure. State Engineer may disapprove determinations of division engineers.

Heard testimony of George G. Anderson and Charles W. Comstock. Have examined and considered transcript of that testimony and various exhibits offered in connection therewith.

As to Exhibit A-32, presented by Mr. Anderson, my attention attracted by Mr. Anderson's statement that average annual storage about 57,000 acre feet. Having made previous examinations of the efficiency of Lake Cheesman, I thought this must certainly be an error. Examination of Exhibit A-32 shows amounts of estimates very much too high. We have not sufficient data to examine critically all of the years. Data quite complete from years 1909 to 1913.

1909 year of large flow, certainly yielding full reservoir.

1910 examined in connection with weekly reports of water commissioners. For 1910 weekly reports of water commissioners show that latest ditch receiving water in District 2 between April 2nd and end of year was Burlington ditch, and from April 1st to October 31st it received only at rate of 150 cubic feet per second. Therefore no water could have been stored in Lake Cheesman during that period.

Weekly reports of water commissioners in 8 show that Highline ditch receiving an insufficient supply; therefore at least 10,000 acre feet should be deducted from Anderson's estimate for 1910. This is probably too small a deduction, because Anderson made no adequate provision for direct flow rights of the Water Company.

As to 1911, water commissioners' reports for District No. 1 show that no water could have been stored in Cheesman between May 1st and November 7th. Water commissioners' reports for District 2 show the same thing. Water commissioners' reports for District 8 show that no water could have been stored between April 1st
583 and October 1st. In July, 1911 commissioners' reports show a serious shortage in Districts 1, 2 and 8. Also storage allowed by Anderson for October should be partially reduced, and from his total for 1911 18,000 acre feet should be deducted. And if proper consideration given to demands for direct flow rights of Water Company, the storable quantity should not exceed 9,000 acre feet in 1911.

As to 1912, the demand was such, as shown by water commissioners' reports, that amounts estimated by Anderson should be largely reduced. Demand is the quantity of water necessary to supply the needs at the particular time, limited by the amount of the decree. Unsupplied demand is the difference between what the ditch actually got and what would be necessary to fill its needs. When I speak of demand in reference to districts I mean unsupplied demand.

According to water commissioners' reports in District 8 for 1912, Creesman storage estimated by Anderson for May should be entirely eliminated, for June almost entirely, for July reduced only for week between July 20 and 27, and for August for week between 17th and 24th. No water could have been stored in the last week of August. All of September, and all of October up to the 19th should be eliminated. Anderson's figures 65,000 acre feet in excess of what it should be. As sufficient allowance not made for direct flow rights of Water Company, in my opinion at least 80,000 acre feet should be deducted.

As to 1913, had not seen Mr. Anderson's Exhibit A-32 until this moment. Nevertheless, can examine it just the same. I can say at this time that storage for 1913 should not have been more than 34,592 acre feet.

It therefore appears that for all the years which we can critically examine, figures in Exhibit A-32 are very much in excess of what could actually have been stored. Therefore it is reasonable to assume that all of the other years contained similar errors, the method of calculation being the same. (Motion to strike out assumption granted.)

As to years prior to 1909, examined all years except 1900 and 1909,

in each of which flow was so large as to certainly fill reservoir. From an examination of all of the other years I found that the estimates in Exhibit A-32 were "very much in excess of what they should be."

Prior to 1909 the records are less complete than they are subsequent to that year. Omitting 1900 and 1909, the other years prior to 1909, according to my estimate, were such that the storages estimated by Mr. Anderson in Exhibit A-32 were 25% in excess of what they could have been, deducting which from his average annual storage leaves 43,570 acre feet.

584 Also examined the tables furnished in connection with the testimony of Mr. Comstock, particularly Exhibit A-54. Examined somewhat more extensively than A-32. This examination covered years 1909 to 1913. For reasons given in connection with Exhibit A-32, found average excess 28%. To be liberal, called it 25%. 1909, full reservoir. 1910, must eliminate all storage for May, all for June, all for July, all for August, and first 15 days of October. Deducting these amounts leaves 43,480 acre feet.

In 1911, must eliminate all storages for May, June, July, August, September, October and a portion of November, also storages between April 11th and April 20th, making in round numbers 40,000 acre feet to be deducted, leaving approximately 13,000 acre feet as possible storage for that year.

As to 1912, a year of large and steady flow, but discharge so evenly distributed amount storable less than one would suppose. It was a year of very satisfactory supply. Ditches received water in a very satisfactory manner. This year more nearly approached the ideal condition for direct irrigation than any of the other years mentioned. If equal amount of water had flowed in a more erratic way, more water could have been stored; less water would have been diverted in periods of low flow for direct irrigation, and a greater surplus would have existed during extreme high floods.

In 1912 Cheesman could not have been filed. There must be eliminated from Comstock's estimate 70,672 acre feet, leaving 72,976 acre feet as possible storage in the year 1912.

As to 1913, deductions should be made from Comstock's estimate as follows: May 1814 acre feet, June entire estimate, July entire estimate, August entire estimate, September 12,222 acre feet, total 64,956 acre feet, leaving 46,860 acre feet, maximum possible storage for 1913. Even in these figures, sufficient consideration not given to Water Company's direct flow rights.

As to percentages of excess shown by Comstock's estimates, 1910 15%, 1911 35%, 1912 10%, 1913 40%; average percentage over 25%. Reducing Comstock's average possible annual storage, 62,979 acre feet, by 25% leaves for the corrected amount 47,234 acre feet, as compared with corrected amount for Anderson of 43,000 and odd acre feet. The difference is not so great considering the different methods. Difference probably accounted for by Comstock's taking stream flow corrected for actual Cheesman storage, which Anderson did not do.

As to 1912, in criticising Anderson's Exhibit A-32 I deducted 80,000 acre feet. I desire to correct this. The amount to be

eliminated should be 75,000 acre feet, leaving percentages
585 of excess on Anderson's figures in Exhibit A-32 as follows: 1909 no per cent, 1910 20%, 1911 70%, 1912 5%, 1913 50%, making an average percentage of excess for those years of 29%, which I have taken as 25%.

As to Anderson's figures, Exhibit A-32, for year 1913, upon consideration of water commissioners' reports found that between May 10th and October 10th no water could be stored, leaving as possible storage for that year 33,668 acre feet.

Exhibit A-52, Comstock, also examined and analyzed. Table 1, error to omit Epperson, or Green Valley, ditch, with a decree of 2.25 cubic feet per second. Also in error as to decree of Platte Water Company's ditch; first decree at least 34 cubic feet per second, figured from data given in decree; second decree should be 43, instead of 13, second feet, if interpreted like that of the Platte Canon ditch.

Exhibit A-52, table 2, shows actual diversions without allowing for unsatisfied demands. Unsatisfied demands in Platte Water Company's ditch (City ditch) not very great. Users generally purchase 1 inch to the acre, that is 1 cubic foot per second to 38.4 acres. I have assumed that actual diversion under City ditch represents needs. Exhibit A-52, table 3, shows actual diversions, but not needs or desires. I assume average diversion to represent demand. A-52, table 4, assumes average diversion represents demand; table 5 assumes average diversion represents demand. Table 6, Brown ditch, supplied by seepage and inflow, places no demand on canon, and therefore eliminated in my determination.

A-52, table 7, Last Chance ditch, average diversion shown less than actual demand.

A-52, table 8, Northern Colorado (Highline) ditch, frequent unsatisfied demand; average diversion shown does not represent this. In my opinion demands of this ditch 75,000 acre feet per annum. I have assumed this figure as "being the desires of this canal." A supplemental reservoir supply which Highline now has possibility of securing will increase demand for direct supply. This will curtail the amount which can be stored in Cheesman.

In my determinations I have used the averages shown in Exhibit A-52, tables 2 to 5 inclusive, as showing demands for those ditches respectively. Have excluded average in table No. 6, the Brown ditch, and have used the average for the Last Chance ditch shown on table 7. Have given a modified figure for the Highline, shown on table 8. Have also eliminated Petersburg ditch, table No. 4, as placing no demand on the canon.

586 Exhibit A-52, table 9, excepting the Brown and Petersburg ditches, nearly all water required by ditches here listed must come from canon. Therefore 1909 required 274.25 cubic feet per second, and 1913 313 cubic feet per second of canon water. Distributing this according to Comstock's monthly percentages gives amount for each month of 1913 more than he allows for both districts 2 and 8, and for 1909 slightly less than he allowed for both

districts, showing that his estimate of amount of canon water required to supply these priorities "was very much too low."

Exhibit A-52, table 10. This table does not appear to permit of means or averages being taken, because all ditches are not reported upon in each year. Only the more recent years should be taken. Moreover, in many years there was an unsatisfied demand. Taking the average of the last five years we have an average annual diversion of approximately three acre feet per acre. This period includes two years of low flow when there was a large unsatisfied demand.

The use of three acre feet per acre does not seem to me unreasonable, considering the character of the farms and crops and the fact that these are very old ditches and "can get water when they want it and need it." "I have known many old ditches which used 9 and 10 acre feet per acre, and still holler for more, but such a use, of course, of nine acre feet is excessive." My experience is that where people get three acre feet per acre, it is generally an ample supply, but not an excessive supply.

As to needs of District 8, taking average diversion for the City ditch, Nevada ditch, Platte Valley ditch and Last Chance ditch, omitting Brown and Petersburg ditches, assigning 66 second feet to direct flow rights of Water Company, assuming needs of Highline to be 75,000 acre feet, annual demands on canon would be 156,210 acre feet. This is about twice Comstock's allowance.

Exhibit A-52, table 11. In view of my criticisms on table 10, this table is of no value, being based on annual consumption of 76,000 acre feet, as against 156,210 acre feet as determined by me.

Exhibit A-52, table 12. Table incomplete; does not show gain in some months and loss in others. Showing algebraic sums only. To make table of value, should take gain or loss for each day in year. Otherwise, you have gain in one day held over to make up loss in succeeding day, which, of course, is impossible. Water already gone by cannot be diverted in the ditch. Defendants' Exhibit 29, prepared by me, covers same period as Exhibit A-52, table 12, and shows gain or loss by months.

587 Said exhibit explained. If monthly gain or loss had been considered, and gains ignored, the average of loss between the two stations would have been 71,013 acre feet, instead of 49,542 derived from Comstock's Exhibit A-52, table 12. And using the monthly basis and ignoring gains, the average loss during the months of irrigation between the two stations would have been 58,605 acre feet.

Exhibit A-52, table 15. As State Engineer, I have established the making of seepage measurements. Seepage return is a very important item in the use and in the supply of water in the South Platte drainage. Water returned to river from Denver sewers or from any tributary not included in seepage. Seepage return is at a fairly constant rate throughout the year, although there is some variation at certain periods.

Exhibit A-52, table 15. Error to apportion tributary inflow on same ratio as seepage between upper and lower District 2. More tributary inflow in lower than in upper District 2.

Exhibit A-52, table 13. Three acre feet per acre does not seem an excessive amount. It is ample, but I would not consider it wasteful, because a large part of the land under these ditches in District 2 is gravelly, and most of the ditches are quite old.

The use or duty of water depends upon acreage handled. Water handled more economically on large acreages. Duty of water influenced by reliability of supply. If ditch likely to be shut down later in season, users will divert every bit that they can get in the early portion of the season, in effort to tide over inevitable dry period. So in ditches like Highline users will divert early in season all the water that they can get the soil to hold.

As to upper District No. 2, I believe that 135,000 acre feet annually would supply the necessities.

Exhibit A-52, table 16, same objection as to table 15, although possibly error not so great, as district quite short.

According to my estimate, demand for District No. 8 upon the canon annually amounts to 156,210 acre feet. Apportioned to the several months of the irrigation season, and excluding the 66 second feet required for Water Company's direct flow rights, this would be: April 90 second feet, May 261 second feet, June 450 second feet, July 438 second feet, August 349 second feet, September 180 second feet, October 90 second feet. To this the Water Company's 66 feet must be added for each month. The percentages used are: April 5%, May 15%, June 25%, July 25%, August 20%, September 10%, October 5%. In this vicinity the demand for April is not a
588 very great amount, but approximately five per cent of the season's demand. The figures given are the demands of District No. 8 upon the canon.

As to District No. 2, I have analyzed demands for 1912 and 1913 as shown by reports of water commissioners. Have taken into consideration inflow between canon and Denver; and have taken flow of stream past gauging station at Denver at such times as Burlington was receiving no water, or insufficient supply, as showing demand. When Burlington is getting all it needs rest of district is supplied. It may be assumed that the amount past Denver, with the Burlington insufficiently supplied, less seepage and tributary inflow in District 8, represents demand of 2 on canon. Taking water commissioners' reports, demands, inflow and records of stream flow at stations, I arrive at certain figures which in my opinion show the average demand each month of the irrigation season of District No. 2 on District No. 23 through District No. 8.

I took the years 1912 and 1913 as indicating the demand; took the stream flow on the same day when the water commissioners reported, on this point taking the hydrographers' reports instead of water commissioners' reports. For 1912 witness gives figures on diversion of water and demands in District No. 8 as stated in water commissioners' reports.

For 1912 witness gives figures as to diversion and demand purporting to be from water commissioners' reports.

From the figures that I have given as to demand of District No. 2 and District No. 8 it is necessary to deduct the amount of return

flow in District No. 8 to arrive at demand on canon by District No. 2. I will reduce the figures which I have given to tabular form.

It is necessary at some time of the year to fill Barr Lake. That lake would naturally try to get water, if it was available, in the fall.

My figures of demand of District No. 2 on District No. 8 are as follows: April 150 cubic feet per second, May 400, June 700, July 700, August 500, September 300, October 300, November 300, December 150. As to seepage and return flow in District 8, which must be deducted, as shown by water commissioners' reports for 1912 it was: April 221 second feet—this is greater than the demand, which eliminates April—; May, seepage and return 231 second feet, leaving 169 second feet; June 106 second feet, leaving 594 second feet; July return 106 second feet, leaving 594 second feet; August return 106 second feet, leaving 394 second feet; September return 113 second feet, leaving 187 second feet, October return 137 second feet, leaving 163 second feet; November return 117 second feet, leaving 183 second feet; December return 103 second feet, leaving 589 47 second feet. These figures are for the year 1912 in both districts. Adding them together we have total demand on canon for both districts as follows: January 66 second feet, February 66 second feet, March 66 second feet, April 166 secon- feet—in round numbers 150 second feet—, May 510 second feet—in round numbers 500 second feet—, June 1180 second feet— in round numbers 1000 second feet—, July 1160 second feet—in round numbers 1000 second feet—, August 735 second feet—in round numbers 700 second feet—, September 433 second feet—in round numbers 400 second feet—, October 329 second feet—in round numbers 300 second feet—, November 249 second feet. I concluded to eliminate ditch demands in November and December, leaving for November 66 second feet, December 66 second feet, being the demand of the Water Company for its direct flow rights. The figures I have given for the demand are almost twice as much in each month as those of Mr. Comstock, accounted for in part by 66 cubic feet per second, demand of Water Company direct flow rights. Other differences due to fact that Comstock took actual use rather than demand, including possible unsatisfied demands, as his basis.

With foregoing figures of demand as basis, I have determined quantities storable at Lake Cheesman, taking as a basis of supply Comstock's figures shown in Exhibits A-53 and A-54. For 1900, a year of large flow, reservoir could have been filled. For 1901, records being incomplete, I have assumed that average storage could be made, the year being one of approximately average flow. Have therefore estimated 50,000 acre feet possible storage.

Exhibit 30 is a compilation of possible storage, beginning with the year 1902. Exhibit 30 explained. Basis: discharges at Lake Cheesman, as shown by Comstock in Exhibits A-53 and A-54; hydrographic records in State Engineer's office for 1900 to 1913; demands on canon, as shown by me, for Districts 2 and 8; these demands deducted from stream flow at South Platte before storage permitted at Cheesman; excess assumed storable at Cheesman, to

the extent that recorded stream flow in South Fork would furnish same.

1902: took Comstock's figures for January and April; February, estimated, in absence of record of stream flow at South Platte—also March; April to October inclusive, calculated on my estimate of demands and recorded stream flow; November and December, estimate, in absence of recorded stream flow.

In 1903: January and February estimated, in absence of recorded stream flow at South Platte; March and April, took quantity of actual storage as shown by Water Company records; May
590 to December inclusive, calculated on my estimate of demands and recorded stream flow.

December, 1903, quantity withdrawn by company may have been withdrawn to keep river channel free from ice, which was their custom.

Subsequent to March, 1908, used corrected stream flows as shown by Comstock's Exhibit A-53; figures for inflow at Lake Cheesman taken from report of engineers of Public Utilities Commission.

Exhibit 31 is copy of table found in report of public utilities engineers, showing inflow and outflow at Cheesman.

Exhibit 30, year 1904. January and February, Comstock's figures; March, took actual storage; April to November inclusive, calculated on my estimate of demands and recorded stream flow; December, actual storage.

1905. Year of comparatively large flow. January, February, March, April, November and December, Comstock's figures; May to October inclusive, calculated as before stated.

1906. Practically no actual storage occurred. January, February, March, November and December, took Comstock's figures; April to October inclusive, calculated as before stated.

1907. A year of quite large flow. January, February, March and December, took Comstock's figures. Other months calculated as before stated.

1908. Comparatively low flow. January, February, November and December, took Comstock's figures. Other months calculated as before stated.

1909. Not specifically analyzed. Year of very large flow. Reservoir could have been filled to capacity.

1910. January, February and April, took Comstock's figures. Other months calculated as before stated.

1911. Year of comparatively small discharge. All months calculated as before stated.

1912. A year of quite large flow, but of comparatively uniform flow, as previously stated. For December took Comstock's figures. Other months calculated as before stated.

1913. South Platte records not complete. January, February and March, took Comstock's figures. Other months calculated as before stated.

Recapitulation of estimated possible storage at Lake Cheesman: 1900, 79,064 acre feet; 1901, 50,000 acre feet; 1902, 11,888 acre feet; 1903, 19,336 acre feet; 1904, 24,639 acre feet; 1905, 78,490

acre feet; 1906, 70,344 acre feet; 1907, 72,088 acre feet; 1908, 11,390 acre feet; 1909, 79,064 acre feet; 1910, 47,408 acre feet; 1911, 9,830 acre feet; 1912, 75,876 acre feet; 1913, 47,906 acre feet. Average 48,480 acre feet.

591 This average is probably too large. On reviewing water commissioners' reports find that, especially in years 1910 to 1913, I have estimated possible storages when water commissioners were reporting shortages in Districts 8, 2 and 1. Also, I have not allowed for evaporation and other losses. My opinion therefore is that 45,000 acre feet represents the greatest possible average storage. This, however, is not the average possible delivery.

Exhibit 32 is a tabulation of the result of the operation of Lake Cheesman upon an assumed annual draft of 40,000 acre feet, according to my estimates of possible storage, covering the years 1902 to 1913 inclusive, again excepting the year 1909, in which year, because of large flow, the reservoir certainly could have been filled.

Exhibit 32 explained.

The figures for possible storage there given are from previous Exhibit 30. Withdrawals from reservoir, May to October inclusive, according to percentages determined by Mr. Comstock from an examination of diversion of ditches in District 8, to-wit: May 15%, June 25%, July 25%, August 20%, September 10%, October 5%.

Exhibit 32 further explained.

Exhibit 29, 30, 31 and 32 admited over objection and exception.

As to value of water rights:—Stored water particularly valuable, because it can be used at user's pleasure and to accomplish the greatest good, and at periods when there would be a shortage in the river for direct flow; available at those times of the year when ordinarily the river is low. The more valuable crops, generally speaking, require water late in the season. With storage water the user can raise any kind of crops; not limited in that respect by the stream flow. He can also use stored water when direct appropriation fails him. Stored water has its greatest value as a supplemental supply; that is, a supply supplementing a direct flow right. In determining the value of water, we must determine the period of the irrigation season when it is to be used. An acre foot of water used in June is not as valuable as an acre foot of water used in August. The supply being great in June and short in August, the price is higher in the latter month.

I have for a number of years been considering the value of water in Colorado. In my investigation and reports on proposed irrigatin projects I have had to assume some values for determining feasibility. In that way I have an idea of the value of water. Have taken into consideration character and amount of crops, value of lands, revenue to be derived from farming operations, sell-
592 ing price of land with water, selling price of water alone, and especially the price which the user can afford to pay and make his farming business profitable.

Value of water is not the difference between value of raw land and value of land and water united, with the land cultivated, fenced and improved. Must consider value of improvements, time that

has been spent by the farmer in bringing it to a profitable basis; also that some inducement must be offered to the farmer to go out and take up raw land, spend several years thereon, etc. In considering feasibility of projects, always tried to consider ultimate user of land, and felt it necessary to offer farmer inducement other than bare living. Value of water limited by price which farmer can afford to pay—that is maximum.

Investigation in Poudre Valley resulted in conclusion that average production or gross yield was $50 per acre. Cost to produce about $25 per acre. Considering taxes and the like and allowing ten per cent on the investment, land producing such crops would be worth $200 per acre. Cost of putting land into condition as follows: Cost of raw land $40 per acre; fencing $15 per acre; improvements $40 per acre; water rights $75 per acre, profit $25 per acre, total $200. The profit of $25 per acre is the inducement to the farmer for his time and work and interest during construction. Think value of farm should be divided equally into three elements, land, water and improvements (including farmer's time); this would produce about $70 for each element per acre.

Assuming land with water in the vicinity of Denver to be worth $200 an acre, that would contemplate an ample water supply, and would require as a minimum two acre feet per acre, and probably two and a half acre feet per acre to accomplish the greatest good. Under existing canals in this vicinity which have a good right the use is, I think, generally three acre feet per acre. Value of water by months: May and June, $12 to $15 per acre foot, on the basis of value of the Highline rights, but as this supply even in those months is irregular, say $25 per acre foot. As the season advances the value increases. In August the value would be $50 per acre foot, but if delivered throughout the irrigation season $40 per acre foot, which I have taken as the value of water in Lake Cheesman delivered in that way. If, however, the water was all delivered in the latter part of July, August and September, when the water was of more value, I should place the value per acre foot at $50. Therefore, as a supplemental supply Lake Cheesman water in my judgment would be worth $50 per acre foot; as an entire supply from $35 to $40 per acre foot, measured at the headgate of the canal. 40,000 acre
593 feet at $50 each makes Lake Cheesman as an entity, including structures, worth $2,000,000.

Direct flow rights differ in value and in characteristics from stored waters. Stored water may be used at any time. Direct flow rights must be used when the water is in the river. If, not, then use is passed on to the next user. The character of crops may be changed by the necessity of using water during certain periods of the year and not having enough water at other periods, when other crops might be grown. Stored water may be carried over. If one has a surplus in one year he may carry it over into another, which of course cannot be done with direct flow rights. Direct flow rights if there is probability of shortage later in the season, are sometimes drawn upon to a greater extent than otherwise they would be. Stored water, when the alfalfa, for instance, is being harvested, can be held

until later and until it is needed. In such a case the direct flow rights get past down the river and go to other people and the owner would get no benefit. There is such a wide difference in the value of the two that the value of the two is very different. It would give incorrect results to estimate the value of direct flow rights on the basis of acre feet. You have not the same latitude of use in direct flow rights as in reservoir rights; your possibilities are limited; you must use it when it is flowing in the stream; you cannot save it for other periods of the year or for other years. You cannot figure a direct flow in terms of acre feet, any more than you could figure the value of an acre foot of water in storage on the basis of the value of a direct flow; the two things are so different.

As to the value of Platte Canon rights and Marston Lake, I considered these in a group, as Mr. Anderson did. This group covered items 1, 2, 3, 4, 15, 16, 17, 13, 14 and 21 of Exhibit C. Mr. Anderson did not deduct enough from Platte Canon ditch yield to cover Hugens and Shellabarger rights. For these I have deducted 2.86 cubic feet per second, leaving a net for the Platte Canon ditch of 50 cubic feet per second, which I have valued at $4,000 per second foot. I think it is worth that much per second foot. This makes for the Platte Canon ditch $200,000.

For the Platte Canon filter beds, I have valued the average delivery of 10 cubic feet per second at $1,000 each, making $10,000, for the summer flow, and at the rate of $2,825 per second foot for the winter flow, making $28,252, or a total of $38,252 for the summer and winter flow of the Platte Canon galleries.

As to the winter flow of the Platte Canon ditch, for five months that would amount to 14,771 acre feet, which might be
594 stored in Marston lake. The Bear creek rights furnish 6,840 acre feet. These two combined would fill Marston Lake, which has a capacity of 19,794.7 acre feet, which at $40 per acre foot makes $791,788. Seepage and other loss from Marston Lake somewhat greater than from Cheesman. Marston Lake water is somewhat less available than that at Cheesman, and therefore somewhat less valuable.

Total value, therefore, for group 1, $1,030,252, which is $123,534 less than the structure value ($1,153,886) testified to by Mr. Anderson.

As to value of group 2, being items 5 and 6 of Schedule B of Exhibit C, I did not place a separate value on item 5. On item 6 I have placed a value of $1,500 per cubic foot per second. In this connection I have considered what would happen if the right were converted to irrigation use, and also the necessity of changing the point of diversion. At $1,500 per second foot, the total value of this right is $15,000 for the summer flow, and $11,000 for the winter flow, making a total of $26,000; structure value as given by Mr. Anderson $72,980, or about $47,000 in excess of value of water and structures combined as fixed by me.

Item No. 7, Cherry Creek rights. Assumed 8 cubic feet per second can be delivered. Have assigned a value equal to that of Highline ditch water, to-wit, $1,250 per cubic foot, making a total of

$10,000. Winter flow not available; but considered as a continuous flow right to irrigate a certain number of acres, I have assigned it a value of $20,000. The structures existing and necessary to utilize this right, as stated by Mr. Anderson equal to value of $60,000, exceeding my valuation of water rights and structures combined by $40,000.

Item 8, Platte Canal filter galleries. As heretofore stated, I value this right at $38,252, winter and summer flow included.

Items 9, 10 and 11, I accept Mr. Anderson's figures, as follows: Item 9, $24,750; item 10, $30,000; item 11, $1,250.

Summary of valuations: Lake Cheesman, $1,600,000 to $2,000,000, depending on whether water was used for entire irrigation season or as supplemental supply; deducting value of physical property as given by Anderson leaves, in the first case a water value of 573,223 for irrigation purposes, and in the second case a water value of $173,223.

Group 1, $123,866 less than the value of physical property.

Items 5 and 6, $47,000 less than physical property.

Cherry Creek rights, $40,000 less than physical property.

Filter galleries, $27,148 less than physical property.

Or a total of $208,034 less for those items than the values placed upon the physical property.

595 This seems strange. It may be accounted for by an overvaluation of the physical property, or by the fact that such structures as these are not the kind of structures built for irrigation purposes. They are entirely too expensive, and aside from being expensive, they have no added value over the less expensive structures usually built.

Deducting said amount of $208,034 from the excess water right value for Lake Cheesman, on a basis of a total value therefor of $2,000,000, and adding items 9, 10 and 11, gives a net value of water rights of $421,189; or, omitting the negative quantities, a net value of $629,223.

As to possible market for rights: Am familiar with acreage under Highline, under Henrylyn system, and under Denver Reservoir Irrigation Company's system. There is sufficient acreage here to absorb the storage capacity of Lake Cheesman as a supplemental supply. Under the Highline the water would have to be carried through probably 60 miles of ditch; under the Henrylyn through probably 75 miles. Under the Highline the loss in carriage would be at least one-third; under the Henry-lyn about the same. These are averages. From Cheesman to head of Highline ditch loss in stream 5%; from Cheesman to head of Henry-lyn loss in stream 10%. As to stream bed losses, these are estimates. There is not much available data. My answers are based largely on present prevailing custom of deduction for losses in transit. The loss in the stream is larger after it leaves the mountains.

Referring to testimony of Mr. Edwards regarding Larimer and Weld Canal. Total acreage served by that canal is about 40,000 acres. The average amount of water furnished is about 62,000 acre feet.

The majority of the reservoirs in this state are stream-bed reservoirs. Stream-bed reservoirs are able to store the maximum floods, while plains reservoirs are limited by the capacity of the intake ditch. Stream-bed reservoirs require more extensive spill-ways and more careful attention. Inflow and outflow records must be kept. The operation is more complicated. Silt accumulates in a stream-bed reservoir.

Exhibits 33 and 34, tables of supplied and unsupplied demands for water in District No. 2 for the years 1912 and 1913, explained. Made up from reports of water commissioners and from hydrographic data in State Engineer's office. These tables contain matters considered by me in making my estimate of demand on the canon.

Exhibit 33 further explained. "However, in the treatment, I have not considered the unsupplied demand in District No. 1 as demanding water at the canon, though, as a matter of fact, it would at times so demand water and be entitled to it."

596 Exhibit 33 further explained. Letter "A" refers to foot note on last page. Letter "B" likewise refers to footnote at bottom of last page. The Burlington, as a general proposition, demands from 300 to 400 cubic feet per second. The demand of the Highline is practically its capacity. That is the standing request, that the Highline be filled to its full capacity whenever the water is available in the river. In November return seepage would supply ditch requirements in District No. 2, and therefore there would be no demand on the canon from that.

Exhibit 34 explained. In April inflow in 8 would supply ditches in 2, therefore no demand on canon from 2.

Exhibit 35 explained. It is from weekly reports of water commissioners. From consideration of these tables I arrived at a conclusion of amount really necessary at canon in order to supply the demands, the average demand for the month, not for this year alone but as applicable to the years in general. I have considered more particularly the condition of the two critical ditches in the two districts, namely, the Highline and the Burlington. They are both very large, both have comparatively late decrees, and by studying them, as to whether they were or were not drawing water, or whether the water that they were drawing was insufficient or not, we can get a very clear conception, I think, of whether or not there was a surplus in the river at the time. Certainly, if neither one of these ditches was drawing during a period when they needed water, then no water could be stored in Lake Cheesman, and with that conception of the case I have constructed this table.

Now at those times when the Highline was drawing an insufficient amount of water, and where it was not drawing any water at all, we may safely assume that the flow in the stream was insufficient to permit Cheesman to store at all.

Exhibit 35, last sheet, shows final conclusions as to demand on canon each month.

Exhibits 33, 34 and 35 admitted over objection and exception.

As to testimony of Mr. Wiland. The Colorado Canal is ordinarily

referred to as the Bob Creek Canal. Its direct flow rights not very good. Twin Lakes reservoir supplemental supply. Also other supplemental supplies. As to Colorado, or Bob Creek, Canal, I made some investigation of values of water rights. Prices investigated covered both direct flow and reservoir rights under that system. Investigation made in July, 1913. Prices: for ditch rights $30 per acre; for Twin Lakes reservoir rights $20 per acre, and Lake Meredith reservoir rights $10 per acre. Average diversion about one and one-half acre feet per acre per annum.

597 Also familiar with the Bessemer canal mentioned by Mr. Weiland, and value of water under it. Current selling price of water rights $110. Amount diverted about 3½ feet per acre per annum, indicating a value per acre foot of $32. The price for the water is about $110 per acre, and little can be obtained at that price. Mr. Weiland's allowance of $7.50 per acre for the raw land is low for land in that vicinity, where there is any hope or probability of getting water. His allowance of $20 an acre for improvements is also too small.

Cross-examination:

I was not subpœnaed in this case. I have spent considerable time and labor in connection herewith, but not as much as I should like. Employed by defendants for that purpose. Not testifying in capacity as State Engineer. Conclusions here announced not those of State Engineer. They do not necessarily represent what are or would be the conclusions of myself as State Engineer. I reserve the right to arrive at different conclusions in that capacity. Am here using stationery of the State because they were the only blanks I had handy.

State divided into five water divisions; each division into a number of water districts. In each water district there is a commissioner; in each division a division engineer, with the State engineer at the summit of the structure.

Districts 23, 8, 2 and 1 are in Water Division No. 1, or the South Platte division, of which Filmore Cogswell is division engineer, and has been for six years.

Division engineers appointed by Governor; water commissioners by Governor, on recommendation of board of county commissioners. Water commissioner's duties confined to his district. Division engineer's duties relate to disputes between districts. He may also determine disputes between users in one district, and reconsider determinations of water commissioners. In all cases there is a right of final appeal to State Engineer. In that respect State Engineer occupies a judicial, or quasi judicial, office.

Matters which I have here testified about might come before me as State Engineer. As an illustration, I as private water user under City ditch called attention of City to the fact that interpretation of their decree was incorrect. City applied to me as State Engineer to change interpretation. As State Engineer, I refused, because interpretation had been going on for many years. That illustrates the difference between the individual and the official.

The conclusions I have arrived at in this case will not influence me when these questions come before me as State Engineer. I see no impropriety in my making these determinations and
598 testifying to them in this case, although I am State Engineer. This is so because seven years ago, at the time of the former appraisement, I was employed by the City to make similar determinations, which I then made and reported. The accuracy of my report and determinations was questioned by a good many people. I felt in this case that, because of my former connection with the matter, it was no more than right for me to continue. I had no scruples about it, but felt I had a duty to a previous client to perform. My present determinations will not control my future official action. When in future the right of Lake Cheesman to store comes before me as State Engineer the matter will be determined upon actual conditions existing at the time.

The quantity storable at Cheesman varies greatly from day to day, from month to month, and from year to year. These variations are caused by sudden floods and rises in the river and its tributaries. Sometimes last for a single day, or for two days, or for only three days in succession. Also demands of individual ditches are exceedingly variable dependent upon condition of precipitation, etc.

I feel that I can approach the decision of such questions as State Engineer with a perfectly open mind, notwithstanding the determinations made in this case; also that there is no impropriety whatever in the State Engineer doing what I have done in this case.

Began preparation in this case after hearing testimony of Anderson and Comstock. Prior thereto had made no investigation with respect to the matters which my exhibits set forth. Upon consideration of their testimony and exhibits, was impressed at statement of Mr. Comstock that average deliverable amount in Cheesman was 70,000 acre feet. In 1907 and 1908 I had found it much less. I therefore investigated Mr. Comstock's figures to see how we differed. My effort was to find the error in his process of reasoning. I approached the consideration of Mr. Anderson's testimony and his tables in the same way. I did not make any entirely independent investigation of my own. In arriving at my results I used Comstock's corrected stream flow table from 1908 to 1913. Exhibit 30 sets forth the results thus arrived at by me. I did not use any of Mr. Anderson's figures. In so far as I made any original investigation, the conclusions therefrom are set forth in Exhibit 30.

My former investigation in 1907 was in connection with the first appraised of the Water Company's plant. Was then employed by City to prepare data and present considerations and evidence
599 to the board. Mr. Fellows was also with me in the work and it was done under the name of Field Fellows and Hinderlider.

The data presented to the old board was in the form of statements or reports in writing, signed by myself and Mr. Fellows. We filed three such statements or reports. (Objected to. Objection overruled. Exception.) Also appeared in person before the board to assist Mr. Thomas, the attorney. The city was represented by

Governor Thomas, and I was present at the time arguments were made before the board on the question of water rights. Notwithstanding our efforts and evidence, that board valued the water rights, exclusive of structures, in excess of two million eight hundred thousand dollars. (Objected to. Objection overruled. Exception.) They valued the Lake Cheesman water right, exclusive of structures, at one million five hundred thousand dollars. (Objected to. Objection overruled. Exception.) The old board of appraisers lacked experience in irrigation matters. The men constituting that board were of high standing in the profession, and of very large experience in matters pertaining to water works and water supply for domestic purposes.

In my evidence submitted to the old board of appraisers, the estimated yield of Cheesman was something less than 40,000 acre feet; somewhat less than the estimate which I have here presented. That possibly was true in respect to the other water rights. The water rights then examined were the same as those here involved. The unit prices or values which I then applied were also less than those to which I have now testified.

As hereinbefore stated, the reports which I submitted to the former board of appraisers were criticised in a professional way. That occurred at a meeting of the American Society of Civil Engineers. The criticism was that the appraisement was entirely too low. I felt that I was at a disadvantage at that time because I had not been given sufficient time to prepare.

Mr. George Anderson was also a witness before the board of appraisers. I have criticised the testimony and tables which he has submitted in this case.

Since submitting my report to the old board of appraisers I have really made no further investigation of the matters involved except in this particular hearing. For this hearing I have spent perhaps four days in the court room before I went on the stand; probably fifteen or eighteen days outside of office hours. A good many of these were nights. If I had had more time it would have been of benefit. With more time I think I would have been able to get down to allowances of quantities below my present estimate.

600 I am quite positive that lack of time has not led me into the error of assigning too low quantities. Not all of the time spent by me in preparation was at night. There were Saturday afternoons and Sundays. At the rate I work I count Saturday afternoon a day. I am a rapid worker and I believe I accomplish as much in half a day as an ordinary engineer would in a full day.

The criticism of my former report may have entered in a small way into my determination to testify in this case, for the purpose of justifying my former conclusions. Did not feel called upon to justify my former report, but felt that I had a duty to an old client to perform.

In my present investigation I made no use at all of data which I had collected and the conclusions which I had drawn therefrom in my former report. I made no reference at all to my former report; did not review it or look at it, and made no use of data which I

had then gathered, except so far as I had independent recollection thereof; and nevertheless made all my preparations for this case in a period of about fifteen or eighteen days.

As to estimated possible storage at Cheesman, the eliminations which I have made from the estimates of Anderson and Comstock are based upon my investigation of the water commissioners' reports. In constructing my Exhibit 30 I used the weekly reports of the water commissioners almost exclusively. After constructing it I examined their bi-weekly reports. The bi-weekly reports are more complete. They tend to show that my allowance as to the storable amount in Cheesman was probably excessive. When I made eliminations from the estimates of Anderson and Comstock, I did so because in my judgment, based upon my construction of the water commissioners' reports, such storages could not have been made at those times.

As to Anderson's Exhibit A-32, I gave specific consideration only to the years 1909 and 1913. My present judgment is that in testifying on direct examination I said the same thing in respect to the various years and the various months of each year relative to Anderson's Exhibit A-32 and Comstock's Exhibit A-54.

In commenting on Anderson's Exhibit A-32 I stated, as to the year 1910, that there could not have been any storage for part of the months of April, and for all of the months of May, June, July, August, September and October, and that for the year 40,000 acre feet only could have been stored, whereas in my Exhibit 30 I have estimated a possible storage in April, May, July and August, and a total possible storage for that year of 47,408 acre feet.

601 I have not taken the water commissioners' reports at their face value. I did not do so even as to the weekly reports of the water commissioners, upon which exhibit 30 is based.

As to the year 1911, I did not take into consideration the fact that the Antero reservoir stored approximately 11,000 acre feet. The priority of that reservoir is subsequent to Lake Cheesman.

My estimate of storage at Cheesman in 1911 is 9,000 acre feet only, about 1,170 acre feet less than the quantity of actual storage at Antero. The quantity stored at Antero did not appear in the recorded stream flow at Cheesman. If that storage at Antero occurred at times when storage was proper, then it should be added to my estimate of possible storage at Lake Cheesman, and the storable quantity at Cheesman for 1911 would be at least 20,000 acre feet. That is true unless my estimate of demand on the canon for the winter months is too low.

Anderson's Exhibit A-32, 1912. In criticising the same I finally stated that only 75,000 acre feet should be deducted from Anderson's estimate for 1912. That would leave 79,286 acre feet as possible storage. That is more than enough to fill the reservoir. Therefore for that particular year there is no deduction to be made from Anderson's final estimate. Therefore I was mistaken when I said that Mr. Anderson made an overestimate of 5% for that year.

In constructing my Exhibit 30 I used only the weekly reports of the water commissioners. In criticising the testimony of Anderson

and Comstock and their Exhibits A-32 and A-54 I had also the water commissioners' bi-weekly reports. In my first comments on Anderson's Exhibit A-32 for 1913, I stated that the total storage for that year could not be more than 34,592 acre feet. From a later examination of that year, in connection with said exhibit, I stated that the storage which could have been made was 33,668 acre feet. In my own Exhibit 30 I estimated for 1913 a possible storage of 47,906 acre feet.

As to 1914, there is no doubt at all that Lake Cheesman could have been filled to its capacity. I did not consider the year 1914 at all. That year has been a year of large flow, and the direct diversions of ditches have been unusually large. If I had included it, it might have increased my estimate of the average demand on the canon. Whether such increase would have occurred, or whether it would have offset the increase in average efficiency of Lake Cheesman, caused by including the year 1914 as a year of full reservoir, I do not know.

As to my estimate of demand on canon, I have not arrived at it by averaging the demands for any particular years. I have not simply put down the figures as they appeared for each year
602 and averaged them, as a matter of arithmetic. I have assumed what in my judgment would be an average demand. But in criticising the tables of Anderson and Comstock I was dealing with the actual demands as they existed each year.

As to Anderson's Exhibit A-32 and the percentages of error as determined by me. In 1909 there was no excess, and therefore no percentage. For 1910 the excess as compared with my Exhibit 30 and the consequent percentage is less than 20%. Exhibit 30 represents my own conclusions. That is quite distinct from the criticism I made of Anderson's report. I offered Exhibit 30 as my judgment of what could have been stored in the years covered thereby, although the estimate is probably excessive.

Comparing my Exhibit 30 with Anderson's A-32 and A-31, his estimate for 1910 exceeds mine by about 5.2%. In criticising Anderson's estimate, my method was to deduct from those months where, according to my Exhibit 30, I thought he had overestimated, but not to add to those months where I thought he had underestimated. I was trying to ascertain Anderson's percentages of error, based upon a consideration of the years 1909 to 1913, and apply that in reduction of his estimate of former years. I consider the method I employed correct for that purpose.

1911, in which I found Anderson's percentage of excess to be 70%, was the year in which the smallest quantity of storage was estimated. Consequently, while the percentage of excess was high, the effect on the total quantity for the period would be exceedingly small.

In my Exhibit 30, year 1912, month August, the total storage should be increased by 1,000 acre feet, making my total estimate for that year 76,876. On those figures, Anderson's is in excess for that year 5%. Moreover, as stated this morning, if I had deducted from Mr. Anderson's estimate only what I now think should be

deducted, there would remain more than enough to fill the reservoir, so that for what year there was no percentage of excess.

For 1913, comparing Anderson's estimates, Exhibits A-31 and A-32, with my Exhibit 30, his excess is 39.4%, instead of 50%.

Comparing the aggregate of the totals of my estimate and Anderson's for the years 1909 to 1913, the excess of his estimate over mine is 17%. If 1914 included, that would be further reduced.

My determination of possible storage for 1901 of 50,000 acre feet was based on fact that stream flows that year were about normal, and that was about the average storable quantity. There
603 was an absence of records of demand for that year. Also the records of stream flows were not complete.

Field's Exhibit 30 compared with Anderson's Exhibits A-31 and A-32, year by year. So compared, the excess of Anderson over Field is 9½%, instead of 25%, for the years 1902 to 1908. If the storage actually made in Lake Cheesman in June and July, 1904, as shown by Field's Exhibits 30 and 31, were added to the total storage as estimated by Field for the years 1902 to 1908, there would be a difference in the grand total between Anderson and Field of only 7,596 acre feet. I rejected that actual storage because on my estimate of that demand on the canon of 1,000 cubic feet per second no storage could have been made. My estimate is of the average demand. It may not hold good for each and every day. One must consider all of the surrounding conditions all of the time in determining possible storage, and cannot proceed on glittering generalities about anything of that sort. But here we are attempting to forecast the future by what has occurred in the past.

In Exhibit 30 I have made no allowances for evaporation, but it appears that Anderson did not deduct evaporation from the figures which have been here used for comparison.

Taking the total storage for the years 1900 to 1914 as estimated by Anderson in his Exhibit A-31 and as estimated by me in my testimony and in Exhibit 30, Anderson's average annual storage is 57,108 acre feet, and mine 50,638, an excess of Anderson's figures over mine of 12.8%. Nevertheless, I still think it was fair to say that there should be deducted 25% from the average storage given by Anderson in his Exhibit A-31.

1914 followed the somewhat dry year of 1913, and the diversions of water were somewhat greater on that account.

The determinations in my Exhibit 30 were made with a view to ascertaining the facts concerning the storable water for Lake Cheesman. Anderson's determinations, as shown by his Exhibits A-31 and A-32, were made with that same end in view. Nevertheless, I do not think it fair to compare the results shown by my exhibit with those shown in his.

Cheesman dam not completed until some time in 1904. Prior to that time storage limited by stage of construction.

1902 was an exceedingly dry year and a year of low stream flow. After Cheesman was completed and once filled subsequent actual storage was limited by stage of water in the lake.

As to the actual storage made in June and July, 1904, I do not

know whether there were any complaints by other users of water. Apparently Cheesman was permitted to retain the water so stored.

604 My estimate does not pretend to show actual facts as they existed in the past, but only what may be expected in the future, with demands as they are at present and with stream flows as they have existed in the past.

There is no storage right on the river earlier than Cheesman except Barr Lake, which has a decree for 11,000 acre feet, plus enough water to make up for seepage and evaporation. The demand which I speak of is a demand for direct flow rights, except as to the Barr Lake storage right Generally speaking, any increase in demand in the future must be an increase in existing direct flow rights. Any increase of such rights by court decree is so rare as to be negligible.

I cannot recall any specific instance where storage for use in the same irrigation season has been permitted. The Seven Lakes' decision of the Supreme Court is practically a dead letter. This can only be done by fooling the water officials.

The direct diversion ditches are now more insistant upon their rights, and this has a tendency to increase their diversions at the expense of subsequent appropriators. Increased irrigated area under the older ditches is principally caused by the more economic handling of water and higher duty of water.

If it be true that Mr. Anderson during the winter months stored at Lake Cheesman, and included in his estimate of storage all of the water flowing in the South Fork, and deducted from his estimated yield of the Platte Canon ditch whatever shortages therein were caused thereby, then my criticism to the effect that Mr. Anderson had not given sufficient consideration to the requirements of the Platte Canon ditch in the winter time was not well founded, and to make a direct comparison between his estimates and mine the additional storage at Lake Cheesman thus resulting must be taken into consideration.

In 1912 storage could have been made to the full capacity of the reservoir, although my Exhibit 30 states 76,876 acre feet. Taking the figures stated in Exhibit 30, with 1912 corrected as aforesaid, adding the year 1900 as a year of full reservoir, 1901 with 50,000 acre feet and 1914 as a year of full reservoir; adding also the quantities which Mr. Anderson estimated as stored at Lake Cheesman and deducted from the Platte Canon ditch, and comparing the total thus arrived at with Anderson's total, as shown by his exhibits, for the same period, Field's figures show a reduction from Anderson's figures of 9.4%. Adding the actual storages really made in June and July, 1904, but which were eliminated by Field in his estimate, and Field's figures show a reduction from Anderson's of 7.1%.

As to Comstock's testimony and his Exhibit A-54, my detailed criticism of this covered only the years 1909 to 1913. As to 1910,

605 in criticising Comstock I said 43,480 acre feet could have been stored; in criticising Anderson 40,000 acre feet. I gave my own opinion of possible storage in my Exhibit 30.

The analysis of Comstock and Anderson was a criticism without much of an attempt to arrive at actual figures. Nevertheless, thereby I produced a percentage which I applied to their estimates for previous years and to their average estimates. In my own Exhibit 30 I showed for 1910 a possible storage of 47,408 acre feet.

As to 1911, in criticising Comstock I said there could have been stored 13,000 acre feet, in criticising Anderson 9,000 acre feet, and in my own Exhibit 30, 9,830 acre feet.

In getting at actual facts of the past, in the absence of all of the information that might be obtained if conditions were examined at the time, you cannot get at the actual facts within narrow limits. In criticising Anderson and Comstock I applied the things set forth in the water commissioners' reports to their tables. In my Exhibit 30 I arrived at what I considered to be the facts in respect to the matter for each of these years. But by their methods they did not arrive at total quantities which exceeded my own by any such percentage as 25%. In my Exhibit 30 I allowed storage on certain days when they did not, and on certain other days I allowed more storage than they did on the same days. Nevertheless, I do not think my Exhibit 30 should be used in analyzing my criticism of the estimates of Anderson and Comstock. I did not consider my Exhibit 30 at all in my criticism of their reports.

In my criticism of their testimony and exhibits I made eliminations when according to my assumptions eliminations should be made, but no additions when according to my assumptions additions should be made.

As to the year 1912, in criticising Anderson's estimates I finally stated that the reservoir could have been filled for that year; yet my Exhibit 30 states that there could have been stored in that year only 76,876 acre feet. The fact is that the reservoir could have been filled, and that is the fact in reference to my Exhibit 30, namely, that the reservoir could have been filled in 1912. I have already so testified. According to my assumptions and my analysis, the reservoir could in the year 1912 have been filled to its capacity, to-wit, 79,054 acre feet. That is the fact about it according to my exhibit and my understanding.

As to 1913, in criticising Comstock's figures I stated that the storable quantity should be 46,860 acre feet; in criticising Anderson's that it should be 33,688 acre feet; by my own Exhibit 30 I showed that 47,906 acre feet could have been stored in that year.

606 After thus reviewing Comstock's estimates for 1909 to 1913, I stated on direct examination that a reduction of 25% should be applied to all of the preceding years included in his estimate, from 1900 to 1908 inclusive, and I applied that percentage to his average storable quantity for the years 1900 to 1914, although I did not include the year 1914 in arriving at my percentage of reduction. In making my determinations I referred to the water commissioners' reports for my guide as to the quantity of water needed. At periods when there were no water commissioners' reports I deducted from Mr. Comstock's figures on the basis of an estimated demand. I took the water commissioners' reports at their face value. I dealt with

the exhibits of Mr. Anderson and Mr. Comstock in the same manner. Thereby, in considering Mr. Comstock's exhibit I determined that the average annual storage would be 47,234 acre feet; in considering Mr. Anderson's 43,750, and in my own Exhibit 30 48,380. I arrived at this in the case of Comstock by deducting from his estimate and the average of his estimates 25%. If I had included 1909 as a year of full reservoir, which it was, the percentage would have been 20%. I took the average of the percentages of excess ascertained by my examination of the years 1910 to 1913 and applied that as a percentage of reduction to all of Comstock's estimates for all of the years included therein. I consider this a fair method, notwithstanding the fact that the quantities involved in the various years vary greatly, as, for instance, in 1911, when the quantity was very small. I do not recognize that the only correct method is to compare total quantities by his estimate and by mine, and thus ascertain a percentage. I endeavored to ascertain a percentage of error, and I consider my method correct, although the percentages of excess so ascertained vary greatly from year to year.

As to the year 1912, I have admitted that in my Exhibit 30 the proper figure should be 79,064 acre feet. I assumed Comstock's estimate for 1912 to be 10% in excess, although as a matter of fact both he and I made in that year exactly the same estimate, to-wit, a full reservoir. That percentage went into my average percentage. If 1912 be dealt with as a full year, the average percentage of excess in Comstock's estimate would be 18 instead of 25%. Using 20 instead of 25% to apply to Comstock's average results in a quantity for the average annual storage of 50,383 acre feet. I applied this percentage of reduction even in those years when both Comstock and myself estimated a full reservoir.

The reservoir could have been filled in 1900, 1909 and 1912; also in 1914.

607 I consider it fair to apply a percentage of reduction so ascertained, even to the years when beyond question there could have been storage to the full capacity of the reservoir.

As to Comstock's Exhibit A-52, table 1, the Epperson, or Green Valley, ditch, omitted from that table, is a relatively small ditch and its decreed priority small in quantity. Its intake is near Overland Park and below the intakes of the Brown and Petersburg ditches, which I eliminated from consideration because they receive their supply from seepage and inflow. The Epperson, or Green Valley, should be eliminated for the same reason. Its omission from Comstock's table would in no manner affect the result.

Exhibit A-52, table 1, Platte Water Company's decree. The decree has always been construed as stated in Mr. Comstock's exhibit. In my capacity as State Engineer I now enforce it according to that interpretation, and allowances are made to the ditch upon that basis. In 1897, when I was formerly State Engineer, I was requested to change the construction of the decree, but I refused to do so. No suit has ever been brought to change that determination of the water officials. The present capacity of the ditch is 85 second feet. The present interpretation of the decree, as stated in Mr. Comstock's ex-

hibit, has been in vogue for almost thirty years. As State Engineer, I would not now change it, except in obedience to a court order. The ditch has never diverted in any year since 1889 at a greater average rate than 51 second feet. I would not attempt to determine whether that constitutes abandonment of any greater quantity mentioned in the decree. To prove abandonment is a very complicated and difficult matter.

As to Exhibit A-52, table 2, relating to Platte Water Company's ditch (City ditch), my criticism was that it did not give proper weight to unsatisfied demands. The city itself uses water from that ditch for city purposes, to irrigate some of the parks, etc. As a user of water under the ditch, I am party to pending litigation with the city relative to water rights thereunder. So far as I am concerned, the suit does not involve a dispute as to distribution of water from the ditch between the city and myself. It may as to other litigants. The first decrees only of the City ditch (30 cubic feet per second) is equivalent to one second foot for each 67 acres of the total acreage (2,000 acres) under the ditch. I believe the first decreed priority of the City ditch has never been shut off. It is the very first decree on the river. This ditch diverts at an average of 6.9 acre feet per acre per annum. That includes what is diverted for city uses. The dispute between the city and the farmers is, I presume, based on the claim by the farmers
608 that the city is claiming and using for city purposes too much of the total appropriation. I do not know how much the city uses. I do not know whether the city uses as much water as would be necessary to irrigate a thousand acres.

As to Exhibit A-52, table 3, relating to the Nevada ditch, my first criticism of this was that it did not give due consideration or effect to unsatisfied desires or demands. The diversion by that ditch in 1913 (20,130 acre feet) for the number of acres irrigated (1,900 acres) amounted to 11 acre feet per acre per annum. I consider that an excessive diversion of water. In 1911, a year of low flow, the diversion was 6.8 acre feet per acre per annum. I would consider that under ordinary conditions as an excessive diversion. The average diversion for the years covered by the table amounts to more than 5 acre feet per acre per annum. I consider that to be a pretty good supply. Nevertheless, I hardly think my criticism unjustifiable, to the effect that the table did not give due weight to unsatisfied demands. Old ditches having old decrees take water in large quantities. 20,000 acre feet per annum is an excessive demand and an excessive diversion for 2,000 acres of land. Nevertheless, inasmuch as that rate of diversion does not exceed the decreed quantity, I as State Engineer, even though I might consider that the amount they were using was excessive, would not interfere with the diversion unless I found that they were actually wasting water. However, if I found that they were wasting it, even though the rate of diversion did not equal or exceed the quantity mentioned in the decree, I personally would prevent it. It is not very often done, but it should be done.

The assumption that I made in determining the demand upon the canon which limited the right of Cheesman to store, I assumed that all of the water diverted by the various ditches was actually needed,

and that those actual diversions represented the actual needs, except as to unsatisfied demand.

In constructing my Exhibit 30 I took the estimates prepared by Mr. Comstock, and shown by his Exhibit A-52, as the average diversions of these ditches as the quantities needed to supply prior *prior* rights, except in the case of the Highline ditch, in which case I added something for unsatisfied demand. I assumed that these large diversions made were no more than the ditches needed, because they were actually made and permitted to be made. As to ditches in District No. 2, I did not employ Mr. Comstock's figures but made my own estimates.

As to District No. 2, I determined the total demands of the ditches as shown by the water commissioners' reports, deducted from it the stream flow at Denver at a particular day, and the balance was the unsatisfied demand which must be supplied by water flowing
609 from District 8 into District 2. The unsatisfied demands of those ditches usually represented the difference between what they were receiving and the amounts specified in their respective decrees. That was the deficiency which I made use of in my computations, and I gave no consideration at all to the question as to whether those ditches, or any of them, could at that time actually have diverted or actually have applied to a beneficial use all of that alleged deficiency.

I do not in any of my computations made for the purpose of this case allow to the Nevada ditch more than 10,817 acre feet per annum. Exhibit A-52, table 4, Petersburg ditch. If in 1912, according to the water commissioner's figures, that ditch diverted 9½ acre feet per acre, that may be an excessive diversion. That is possibly more than the ditch ought to require under any circumstances. If that ditch was diverting 9 acre feet per acre per annum, I as State Engineer would permit it if they were not wasting the water. What I mean by wasting it is running it back into the river or allowing it to accumulate on roads or in sinks, but not if they applied it to the land.

In accepting the water commissioners' reports as to the demands of ditches, I have made no investigation to determine what they would mean in terms of acre feet per acre. I took those demands just as stated in the water commissioners' reports, although I made reductions in the quantities in my final estimates.

Exhibit A-52, table 5, Platte Valley ditch. In criticising Mr. Comstock, and in my own computations, I used as the requirements of this ditch 1639 acre feet per annum. 7.5 acre feet per acre irrigated, the diversion of this ditch for 1909 according to the water commissioner's report, seems large. When you are endeavoring to find how much water in quantity a certain amount of land ought to have in any one year, it is proper to express it in acre feet. 7 to 7½ acre *per* feet per acre per annum is not an unreasonable quantity if the farms are small, or if they are gardens, and things of that sort.

Leaving District 23 out of consideration, my judgment is that in the other districts here in Northern Colorado the use of water is about the same. But in considering a small ditch, like the Platte Valley,

having a small acreage under it, it is necessary to know the character of the land, whether gravelly, etc., also the soil and subsoil, the crops raised, and how the land is divided into different holdings. In the absence of differences in these respects the necessary use of water throughout Northern Colorado is approximately the same.

610 As to the Platte Valley ditch, if the water commissioner's reports for 1912 gave an acreage under this ditch indicating a diversion by the ditch of 17.39 acre feet per acre, and if the acreage given be correct, that is an excessive use. The water commissioner's statements of acreage, especially of small tracts, is not as reliable as the balance of his reports. I think the water commissioner's statements of demand are reliable. It is part of his regular and continuous duty to ascertain that.

In making up my estimates for this case I gave no consideration to the matter of acreage, or the diversion of water per acre by various ditches, except in the case of the Highline.

The intake of the Platte Valley ditch is within the city limits of Denver, far down stream from the intakes of the Brown and the Petersburg. The Platte Valley ditch should be eliminated in determining demand on the canon, because it is supplied by inflow and seepage. Nevertheless I included it in making my estimate of demand.

Exhibit A-52, table 6, Brown ditch. I did not look up the number of acres irrigated. I eliminated the Brown ditch in determining demand on the canon, because it is supplied by seepage and inflow.

Exhibit A-52, table 7, Last Chance ditch. I stated that there were unsatisfied demands under the Last Chance ditch because the records show that the ditch has at times been shut down; nevertheless I took the average diversions of the ditch as showing its needs. I used that figure in all of my computations which had any reference to the Last Chance ditch. It was one of the methods I used in getting up my Exhibit 30.

Exhibit A-52, table 8, Northern Colorado Irrigation Company's canal (Highline). I said the demand ought to be the amount which it actually diverted in the years of abundant flow, instead of the average shown on the table. I do not think that the number of acres cultivated under that canal are limited by the quantity of water which the canal can divert and does divert in the average year. There is a greater acreage under cultivation than the average flow would justify. I do not know the actual acreage in cultivation under the Highline. It has been variously stated to me from eighteen to twenty-four thousand acres. I think it is approximately 20,000 acres. On the basis of average annual diversions, that means a little over two acre feet per acre, but there is a large loss in transit. That varies with the distance of the land to be irrigated from the intake of the ditch.

The supplemental supply which I had in mind for the Highline as mentioned in my direct testimony was the Antero reservoir.

611 I stated that the acreage would enlarge because of the reservoir supply, and so increase the demand on the direct appropriation. That would not be so if the supplemental reservoir supply was unable to furnish any water. The Lake Cheesman decree is prior to

that of the Antero. Nevertheless, Antero could fill when Cheesman reservoir is full so that it cannot store. If all the water stored in Lake Cheesman each year was stored and withdrawn, according to my estimates, as shown in Exhibit 30, there would be only three years out of fourteen when Antero could store. Such a supplemental supply as that would not, of course, affect the number of acres irrigated under the Highline as much as a more reliable supplemental supply.

A reservoir constructed at the present time, and subsequent in priority to Lake Cheesman and Antero, would be able to impound some water, because if located where the Two Forks reservoir is, the North Fork supply would be available. Some reservoir water from the Antero has been run through the Highline for the last year or two.

There has been a vast change in conditions since 1889 and the years prior thereto in respect to appropriations for storage or all-the-year-round rights. After the Lake Cheesman and the Antero priorities there come a number of other priorities for storage purposes, which take their waters from the South Platte river. According to my estimate here made, Lake Cheesman, having the earliest storage priority on the river with the exception of Barr Lake, could be filled in only three or four years out of a period of fourteen. Therefore a reservoir which comes in after the Antero and Cheesman and these intervening appropriations which have been made since 1889 would not have as good a chance to store, but there have been estimates made, and carefully made, that show there could be quite a little water stored in the Two Forks reservoir. I think "The Last Chance" would be a fair name to apply to such a reservoir.

Exhibit A-52, table 9 does not show an average of the two years. My statement in that regard on direct examination was a misapprehension. I had no occasion to use those figures, therefore gave them no critical examination. In considering this table I took the total diversions for the year 1913 and deducted therefrom the diversions of the Petersburg and Brown ditches, and in my cross examination have stated that the diversion of the Platte Valley ditch should also be deducted, making a total elimination, to offset seepage and inflow, of 14 second feet.

The intake of the Platte Water Company's ditch is three miles below the canon. It would have the benefit of some seepage and inflow. The Nevada ditch is still further down, and its intake is below Deer Creek, near Haworth's bridge, which is the point at
612 which seepage measurements are taken. There is a large accretion by reason of seepage and inflow at that point. I think, however, I have made proper allowance for seepage and inflow in entirely eliminating the Brown and Petersburg ditches and in measuring the needs of the other ditches by their actual diversions.

It was not seepage, rather than generosity and liberality, that controlled my conclusion in adopting as the needs of the ditches their actual diversions, but to say that my generosity and liberality was considerably diluted with seepage and return flow is a very nice way to put it.

As to the year 1913, Mr. Comstock testified that after permitting all the storage in Cheesman that he had estimated for that year,

there would be flowing in the river past Platte Canon 189, 230 acre feet, considering the stream flows for that year, which is very much above his minimum provision of 105,000 acre feet.

As to 1909, Mr. Comstock testified that after filling Lake Cheesman as he had estimated, there was left a total of 337,014 acre feet which would have passed Platte Canon in that irrigation season.

I assumed that all of the water that was diverted in 1909 through the intakes of the ditches was actually needed for the proper irrigation of lands under those ditches.

Review of Comstock's testimony relative to amounts passing down the river after storages had been made in Cheesman, according to his estimates.

If there were a surplus in the stream in any particular month, Lake Cheesman could have stored it, without regard to the fact, if it should also have been a fact, that there was a deficit in regard to the demands of direct flow rights in the preceding month, or that there might be one in the month following.

Rainfall has an influence upon the amount needed under the direct flow rights of ditches. In August, 1908, the rainfall was 3.19 inches, as compared with an average, for the 42 years during which records have been kept, of 1.36 inches. That is the largest rainfall that has ever occurred in the month of August in all those years. In October, 1908, the rainfall was 1.90 inches, as compared with an average of .94 of an inch. Such rainfalls would have a considerable effect upon the needs of direct flow rights.

Further discussion of Comstock's testimony relative to quantities passing down the river after the storages estimated by him, and their excess over the minimum demands of ditches as estimated by him.

613 Exhibit A-52, table 10. I assume that this table covers all the ditches reported upon by the water commissioner for the respective years. I do not know what ditches were not reported upon in any of the years. I do not regard the table as totally unreliable. I would be inclined to use the last few years, when the records were more complete, as giving a fair idea of what the conditions were.

13 or 14 acre feet per acre per annum is more than sufficient for irrigation purposes. I would not want to say that 7 acre feet per acre per annum is excessive. With the exception of the Highline, these ditches in District No. 8 are old ditches, and that is one of the reasons why they divert more water per acre, and still holler for more. The farmer must not waste water, but the courts have determined what he could use—they have given him a decree. So long as he does not exceed the total quantities of his decree, and so long as he does not waste water, in the sense of running it over vacant and unoccupied land or running it back into the river, he is in my judgment entitled to take it. I could not shut his water off on some opinion of my own that he was diverting more water than he needed. The court by its decree has determined that he needed so much. Unless waste is actually occurring, I as State Engineer would not turn off a man's headgate or stop him from taking water

from the ditch at the rate he was taking it, unless that rate exceeded the quantity named in the decree. As an executive officer of the state, I do not give consideration to the question as to whether the total quantity that is being diverted through a ditch is actually really needed for the beneficial use to which it is to be applied. I take into consideration only these two factors: First, what is the decreed quantity as stated in the decree?; second, is this ditch or this man wasting water by flowing it back into the river or flowing it out onto vacant land? If his structures were such that it caused a loss and waste of water, I would take that into consideration. But I would not take into consideration the quantity of water per acre which he is actually putting on his acreage, even though that be a very excessive quantity. I could not impose my opinion as to what constituted a sufficient supply.

As to the duty of water, taking all the lands in District No. 8 into consideration, 3 acre feet per acre per annum would, I think, be a fair average. To reach that average I assigned a higher duty of water in respect — lands outside of the river bottom—such lands as lie under the Highline ditch. The irrigated acreage under the Highline (20,000 acres) constitutes two-thirds of the total irrigated acreage in District No. 8. The land under the Highline ditch is
not river bottom land, but ordinary prairie land, and does
614 not differ in any material respect from the other prairie lands
on the eastern side of the mountains. It is about like our ordinary plains country.

The water districts covering the Boulders, Clear Creek, the Big Thompson and the St. Vrain, including District No. 3, are, broadly speaking, as to the character of the soil, whether gravelly or otherwise, and the proportionate quantities of different kinds of soil, substantially the same as District No. 8. They all lie along the mountain front and are on either side of quite similar streams. They were, geologically, doubtless constructed in much the same way and out of the same materials. These things being true, there is no particular reason why the duty of water should be lower, that is to say, why in District No. 8 there should be more water required in acre feet per acre than in these other districts.

On the older ditches in many of the districts you will find that the use of water is greater than on the newer ditches. There are very old ditches in all of these districts to which attention has been called. As between these several districts there would not be a great distinction in the amount of water per acre which might be used under the same conditions. There are quite a number of reservoirs in District No. 3, there are not a great many in 8. I think the existence of reservoirs makes for economy of use. With reservoirs there is always before the user the fact that if he does not use the water today he may use it tomorrow.

If District No. 8 were as well supplied with reservoirs as District No. 3, the duty of water in District No. 8 would be affected to the extent of ten or twenty per cent, making the average duty in 8 from 2½ to 2¾ acre feet per acre per annum. I do not know the

actual duty of water in District No. 3. That is a very prosperous farming section.

(The attention of the witness is called to the duty of water in Districts 3, 4, 5, 6 and 7, as shown by water commissioners' reports and the reports of the State Engineer.)

The figures as to duty of water which you have quoted to me correspond with figures in the State Engineer's biennial reports. Those figures show a higher duty of water than I had assigned to District No. 8. On the basis of these figures it would appear that 3 acre feet per acre per annum as the average for District No. 8 is excessive, but I think that is more in appearance than fact; first, because the water commissioner's reports as to acreage are inaccurate; second, because all the water used on that acreage is not shown in his reports. In those districts there is a considerable re-use of water. Of the water so re-used a great deal of it finds its way back into the stream before it is again diverted, but a great deal of it is picked up before it ever reaches the stream. In District
615 8 the irrigated area is not so wide and the re-use of water not so great as in District 3. I think the duty of water as shown by the figures in the reports of the water commissioners and in the State Engineers, reports, to-wit, 1.31 acre feet per acre per annum, is really a higher duty of water than the actual performance in district No. 3.

I recently testified as a witness in the case of the State of Wyoming against the State of Colorado. One of the things testified about was the duty of water in District No. 3. I testified that I had made a very careful and complete examination of that question. In that case the object in determining the duty of water in District 3 was to show what the accomplishment might be by the diversion of water from the Laramie water shed into the water shed of the Cache la Poudre. The method employed was first to determine the total amount of water which entered the district, then deduct the seepage and return and outflow, the difference representing the consumptive use. That amount I divided by the total acreage under ditches, showing a consumptive use of about one acre foot per acre. To ascertain the duty of water as ordinarily understood, you would have to add to the quantity of original water entering the district the quantity of seepage and return flow and divide the result by the acreage. I did that also in my testimony in Wyoming vs. Colorado, thus arriving at the actual duty of water.

In the case of the Poudre there is very little water that comes into the river below the mouth of the canon; in District No. 8 there is a considerable amount. In the present case the thing to be determined is how much water must be supplied from Platte Canon, just as in Wyoming vs. Colorado I endeavored to determine how much water was to be supplied at the mouth of the Poudre canon.

In the case of Wyoming vs. Colorado I did not determine duty of water as measured at the headgates of the canals. It would not be as great as my estimate in District No. 8, to-wit, 3 acre feet per

acre. The duty of water in the Poudre is stretched to what we might call the breaking point—it has reached the ultimate.

(His attention is called to conflicting statements in his testimony in that case. See Exhibit A-65.)

(His attention is called to said testimony, Exhibit A-65, as to the method pursued.)

In that case I determined that the total quantity of water entering District 3, both from the canon and from tributaries, was 367,313 acre feet per annum. From that I deducted 120,000 acre feet, being the amount passing out of the lower end of the district, making a net of 247,313 acre feet. That represented the consumptive use of water. 367,313 acre feet represented the original water entering the district.

616

In determining the acreage in District 3 for the purposes of that testimony, I examined the acreage reported by the water commissioners and increased it by about fifteen per cent. For the year 1912 I took 265,000 acres, although the water commissioner had reported only 223,000. Dividing the water consumed in the district, to-wit, 247,313 acre feet, by 265,000 acres, made a duty of water in District No. 3, based upon the amount of original water entering the district, of less than one acre foot per acre, and I so testified. I also testified that the duty might in the future rise to ¾ of an acre foot per acre per annum.

I also estimated the duty of water in that district as measured at the headgates, and stated: "That the real duty and accomplishment which might reasonably be expected will be less than one acre foot per annum, and the use or duty as measured at the headgates of the ditches should be not more than 1.25 acre feet per acre per annum."

(His attention called to other statements in said testimony. See Exhibit A-65.)

The actual performance of water in all these other districts, the duty of water, including my determination thereof as to District No. 3, is a much higher duty and a much greater performance than that which I have assigned to District No. 8. When I said that duties of 7, 8, 9 and 10 acre feet per acre per annum under the ditches in District No. 8 was not an excessive use, I meant that the ditches were not necessarily wasting the water; that the lands under those ditches were different from the lands under the Highline ditch and from the average lands in the Poudre valley, and that the use of 7 acre feet did not necessarily mean a waste, and that 3 acre feet was not an excessive amount. In the upper part of District No. 8 2½ acre feet per acre per annum would be enough.

The water diverted in District No. 8 is used to some extent in adjoining districts, but the acres irrigated as stated in the reports of the commissioners would cover all of the acreage irrigated from ditches having their headgates in District No. 8.

The irrigated acreage in Districts 3, 4, 5, 6 and 7 amounts to about 60% of the total irrigated acreage in the entire Irrigation Division No. 1, and about 25% of the total irrigated acreage of the state.

Water commissioners' reports are unreliable, both in respect to

the acreage irrigated and in respect to the total amount of water used. The county commissioners, almost without exception,
617 refuse to pay the water commissioner for performing his statutory duties, and the water commissioner does not do any more of it than he has to. His pay, unfortunately, is under the control of the county commissioners. As to his appointment, that also is under the control of the county commissioners, for the Governor appoints according to their recommendation. That is the unfortunate part of it. The matter of his selection and the matter of his compensation is practically under the control of the various boards of county commissioners in the respective counties in his district, and the water commissioner himself is a local man, residing in the district. The amount of his compensation is also under the control of the county commissioners with respect to the number of days for which they will pay him. But in the districts here under consideration I cannot say that the water commissioners are not constantly employed. Notwithstanding this, I have made use of the water commissioners' reports as the best information available. The water commissioners are careless about the performance of their statutory duties, particularly in respect to the acreage irrigated, and in respect to failure to report upon all ditches.

Exhibit A-52, table 11.—My statement on direct examination that this table was of no value because based upon an assumption of a use of 76,000 acre feet per annum in District No. 8, was incorrect. I now criticise the table because Mr. Comstock took the flow of the stream for the month at two stations and subtracted, when as a matter of fact he should have taken the flow for each day. In my testimony in Wyoming vs. Colorado I employed the same method as Mr. Comstock has done, but that was for a different purpose. Said table No. 11 leaves out of consideration unsupplied demand. Moreover, in said table No. 11 the losses in the river have been taken by months instead of by days. From said table No. 11, for the year 1912 it results that the demand on the canon to supply the needs of District 8 was 61,130 acre feet. From the testimony of Mr. Comstock it appears that after the storage which he allowed had been made in Lake Cheesman in that year, there would flow out of the canon into District 8 245,632 acre feet, an amount very much greater than my estimates of needs, but I think my estimate of needs was too low.

156,210 acre feet per annum, used by me as the needs of District 8 in criticising Comstock's determinations, ought to be reduced by deducting for the Platte Valley ditch 1,639 acre feet, and for the Platte Canon ditch its winter flow, 24,000 acre feet, leaving about 130,000 acre feet, even on my own assumptions.

Exhibit A-52, table 12.—I criticise this table because it did not ignore the gains by months, but only the gains by years.
618 I criticised table No. 11 because, while it ignored the gains by months, it did not ignore the gains by days.

Mr. Comstock, after a consideration of tables 11 and 12, arrived at the conclusion that a mean annual discharge at Platte Canon of 75,000 acre feet would satisfy the demands in District No. 8. But

that is not as much as I consider necessary for the Highline ditch alone. From table No. 12 it appears that the consumptive use in the irrigation season only would average 58,605 acre feet. Mr. Comstock allowed 75,000 acre feet. Mr. Comstock's method as submitted in these tables was the same as that used by me in the case of Wyoming vs. Colorado, but there I used it for a different purpose.

For the purposes of table 12 Mr. Comstock has used all of the existing reports, but they are incomplete. I have used the same reports in my Exhibit 29.

I think information of the kind tabulated in tables 11 and 12 should be gathered and tabulated day by day. That is because conditions as to stream flow and the needs of the ditches vary greatly within short periods of time, so that it is necessary to determine these things day by day. For instance, there might be a deficiency in the first part of a month, but in the latter part such a surplus that the total flow of the month would be apparently sufficient for the entire needs, whereas, as a matter of fact, in the first part of the month there would be an actual deficiency. Such marked changes in conditions would have an effect on the possibility of storage in reservoirs. For instance, there might be a flood, when even for a single day storage might occur, and yet there might be a shortage in other days. Such floods do occur. The needs of ditches are affected by conditions which are independent of the quantity of water flowing in the stream. Rainfall is one of these. In arriving at my determinations in this case I have not made that analysis day by day, but have assumed an average demand per day for each month.

Exhibit A-52, table 15.—Seepage measurements are so made as to exclude the inflow from tributaries. I think the seepage return is fairly constant. The figures set down in table 15 accurately state the seepage measurements as made. I agree that the seepage return in upper District No. 2 is 55% of the total, and that in 1908 the total was, as stated in Mr. Comstock's table, 340.01 second feet. That would make 248,000 acre feet per annum, excluding inflow from tributaries and from the district above. 55% of that is 137,000 acre feet. The acreage in irrigation in upper district No. 2 being, as reported by the water commissioner, 38,193 acres, the quantity of water which comes back by way of seepage alone would
619 supply 3.6 acre feet per acre per annum. In addition to that, there are the tributaries, such as Cheery Creek, the sewer system of Denver, Clear Creek, Sand Creek, Dry Creek. This leaves out of consideration all of the water flowing down from District No. 8. In lower District No. 2 there are a number of tributaries. The important tributaries which flow into lower District No. 2 are the St. Vrain, the Big Thompson and the Cache la Poudre. The Poudre is actually the boundary between Districts 2 and 1. Its inflow is available in 1 but not in 2. It is not correct to say that the Poudre is a tributary whose waters are available in 2.

There is a considerable discharge from the Denver sewers, some

75%, I think, of the amount that comes in. In seepage measurements it is considered as a tributary, and it is a large tributary.

There is no gauging station on any of these tributary streams, and has never been for any considerable length of time. All any one can do is to estimate their inflow.

If in upper District 2 you add to the quantity of seepage return (137,000 acre feet) the inflow from the Denver sewers (35 or 40 thousand acre feet) and from tributaries (35 or 40 thousand acre feet, that would make a total quantity per annum of approximately 200,000 acre feet, which is much greater than the quantity (122,665 acre feet) arrived at by Mr. Comstock as the quantity returned into upper District No. 2 by seepage and by tributaries. He arrived at that result by taking 55% of the total return for the entire district. A similar result would be obtained by using the average seepage return as shown by table 15, instead of the seepage measurement of 1908. Mr. Comstock's determination of the tributary and seepage inflow into upper District No. 2 was therefore, if anything, too low.

Exhibit A-52, table 13.—It is my judgment that in reality there is actually more water to satisfy the needs in upper District No. 2 than Mr. Comstock estimated. As to table No. 13, my comment was as to the duty of water there shown, and that a duty of 3 acre feet per acre per annum did not seem to me to be excessive.

Exhibit 52, table 16.—My comment on this table would be the same as on table 15, although the possible error would be less because the distance is shorter. I have no doubt that Mr. Comstock has used as his basis the correct figures as shown by the reports. Above the Fulton ditch in District No. 2 there are some important accretions by inflow. I do not undertake to say that by Mr. Comstock's method he determined too great an inflow into upper district No. 2, or into that portion of upper district No. 2 above the Fulton ditch. The principal tributary inflows into upper district
620 No. 2 occur above the Fulton ditch. In my judgment Mr. Comstock's conclusions are not excessive as to what may be expected by way of accretions in that part of upper District No. 2 lying above the Fulton ditch.

As to Exhibit 30, prepared by myself. In that I was trying to estimate the quantity of water storable in Lake Cheesman, first endeavoring to estimate the demand on the flow at Platte Canon, which must be satisfied before Cheesman can store. As to the needs of District 8, I arrived at that by taking the figures of Mr. Comstock as to certain of the ditches and adding 75,000 acre feet for the Highline, making a total for District 8 for the irrigation season of 106,400 acre feet. That amounts to 3.82 acre feet per acre per annum for the acreage irrigated in District No. 8, measured in terms of original water, without considering the effect of inflow and seepage in District No. 8. That is the demand of District No. 8, according to my estimate, upon original water alone. I think it is not excessive. This is so, notwithstanding that I have already stated that the duty of water in District No. 8, measured at the headgates of the ditches, would be an average of 3 acre feet per acre.

What I mean by demand is the quantity which the ditches use, if it does not exceed the quantities specified in their decrees, providing they do not waste the water. The court has already determined for us what is the proper amount—that is determined in the decree. In estimating this demand I do not undertake to determine whether, in accordance with proper irrigation practice, the ditches need such a quantity of water.

The accretions in District No. 8 from seepage and inflow amount in the irrigation season to approximately 53,740 acre feet. Adding this to my estimated demand on the canon results in a duty of water of 5.75 acre feet per acre per annum for the acres irrigated.

In distributing the water used by percentages to the various months in irrigation season, I do not think I made a total of 105%. I did not intend to.

In making up my Exhibit 30, the demands on the canon for District No. 8 as estimated by me were as follows: April, 100 second feet—5%; May, 275 second feet—14%; June, 520 second feet—26%; July, 500 second feet—25%; August, 275 second feet—13.7%; September 180 second feet—9%; October, 100 second feet—5%. Then for each of the months I added 66 second feet to cover direct flow rights of the Water Company.

If in my direct examination I gave percentages yielding a total of 105%, that was, of course, incorrect, and should now be excluded.

Upon this new apportionment, and deducting the Platte Valley ditch, my estimate requires 106,000 acre feet at the canon to supply District No. 8. But computing it according to the rates
621 of flow given, it amounts to a total quantity for those months of 119,300 acre feet. Later I combined these figures with those for District No. 2 and then made a slight reduction in the different months.

As to the demand of ditches in District No. 2, I considered that by an analysis of the water commissioner's reports. I first determined the demands of the ditches, by taking the statements of the water commissioner's reports as to what each ditch received, and also as to what was being demanded and not received. I took the sum of these and from them made certain deductions. The conditions in respect to the Burlington Ditch and the Highline Ditch were really the controlling factors. When these ditches were not drawing water, then the stream flow was insufficient to supply the demand, and therefore insufficient to permit storage. Whenever either one of these ditches was not drawing water, I deemed that to be a period when no storage could occur at Lake Cheesman. When the Burlington and the Highline, or either, was not drawing water, or was not drawing a sufficient amount, then I investigated the water commissioner's reports to ascertain from them what the demands were for unsupplied water. In that way I determined how much more ought to be flowing at the canon than was actually flowing in order to supply the demand. The unsupplied demand was determined on what was reported in the water commissioner's reports. From those statements I made certain deductions. In that respect there are some uncertain elements. I gave so many things consideration that it is difficult for me to state them.

Exhibit 35, sheet 2, referred to as an illustration of the method.

In making my estimate of demand for District No. 2 I have not considered the flow from tributaries, other than the flow at Denver, in the South Platte, except that I have made certain deductions from the demand as reported by the water commissioner. In some instances I increased the demand as shown by the water commissioner's reports, while in other instances I decreased it, because I was working towards an average. I wanted an average which would apply for almost any year, and I studied the particular year in order to help my judgment to arrive at what would be the ordinary demand. I rejected the data for that particular year because the demand in that particular year will not be the average demand. No one year represents an average demand for all years. The determination of that average demand is a matter of judgment.

Exhibit 35, sheet 2, further explained.

When I set down figures differing from the demand as stated by the water commissioner, those figures represented what in
622 my judgment would be necessary on the average, or in ordinary years; partly that and partly what I thought was necessary to supply the needs in a particular month of a particular year. Those elements entered into the determination about half and half. Where I decreased the water commissioner's figures, it was because I wanted to be sure that the demand which I stated was necessary was no more than it really was. Where I increased his figures, it was in an effort to arrive at something of an average.

I made examination here of two years for the purpose of determining by consideration of the two what might be a fair average. I changed the figures with the idea of getting an average.

Exhibit 35, sheet 2, further explained.

In some instances I reduced the commissioner's statement as to demand because I thought it was too large.

Exhibit 35, sheet 2, further explained.

There are large accretions in District No. 2 from seepage and tributary inflow. The demand in District No. 2 will be reflected up the tributary streams, as well as up the main stream.

In my Exhibits 33 and 34 I have shown unsupplied demands in District No. 1, but the quantity of that unsupplied demand and the ratable proportion of it which ought to be supplied from Districts 3, 4, 5, 6 and 7, rather than from District 2, I have not undertaken to estimate.

As to District No. 8, in criticising Comstock's testimony and tables I assumed a demand upon the canon aggregating 106,373 acre feet, leaving out of consideration the diversion for certain ditches, aggregating 6,543 acre feet, because they were supplied by seepage and inflow. The seepage and inflow in District No. 8 is a much greater quantity than that, the seepage return in the irrigation season being about 34,240 acre feet, and the tributary inflow about 19,500 acre feet, amounting in the aggregate to 54,080 acre feet during the irrigation season. All of this, of course, is not available for the ditches higher up in the district, like the Highline.

I made a deduction on account of seepage and inflow in 8 from my estimate of demands in 2. We can, therefore, take up that ques-

tion of seepage and return flow in 8 in connection with my estimate of demands in 2.

In criticising Comstock, I assume the following as the demands of the ditches in 8: May 261 second feet, June 450, July 438, August 349, September 180, and October 90. Deducting the Platte Valley ditch, this means 106,300 and odd acre feet for the irrigation season, for irrigation uses only.

623 In my Exhibit 35, on the last page thereof, my estimate of demands in District No. 8 during the irrigation season, deducting the 66 second feet estimated for the Water Company's direct flow rights, would be as follows: April 100 second feet, producing 6,000 acre feet; May 275 second feet, producing 17,050 acre feet; June 520 second feet, producing 31,200 acre feet; July 500 second feet, producing 31,000 acre feet; August 479 second feet, producing 29,698 acre feet; September 180 second feet, producing 10,800 acre feet; October 100 second feet, producing 6,200 acre feet; or an aggregate, for irrigation purposes only, for District No. 8 of 131,948 acre feet, representing the demand on the canon. As these were the figures which I finally took it appears that I did not accept any of Mr. Comstock's figures as to this demand.

Previously in my cross examination I have given figures for that demand aggregating 119,300 acre feet. That is the figure which I really finally adopted. The difference between that and what is shown in the last page of Exhibit 35 is apparently in the figure for August. For that month I put down 545 for District 8 and then deducted 239 from the sum of the estimates for Districts 8 and 2. I put down as the demand for August in District 8 the average flow at Platte Canon as shown by sheet 4 of Exhibit 35. I considered that to be the demand for that month. For every month except August I wrote down on my final sheet the assumed demand shown on sheet 4, but for August I wrote down the average flow at the canon. In my direct testimony I had stated that 545 was the figure I used, and I wanted to preserve that figure so that the exhibit would conform to my direct testimony. The deduction of 239 second feet is made arbitrarily. The deductions made for other months are relatively much smaller. These deductions were made to conform to the preconceived opinion I had formed as to what might be an average demand.

My Exhibits 33, 34 and 35 deal with this question of demand. The last sheet of Exhibit 35 shows my final conclusions.

In my direct testimony I stated that the facts which I had given relative to demand related to the year 1912, but the figures which I gave related to the year 1913. I got the years mixed, and I think in one case even the districts mixed, reading from my pencil notes. I suppose I drew conclusions in respect to 1912 from figures which pertained to 1913. Therefore my direct examination on that point must be largely disregarded and my tables, Exhibits 33, 34 and 35, examined exclusively as my proper testimony. I stated my conclusions in direct testimony and supported it by details which I now say were erroneous. I now undertake to support the conclu-

624 sions then given by these three exhibits. I found that there was something radically wrong, and so requested that I be per-

mitted to submit these figures. The figures which I now submit as pertaining to the year 1912 are altogether different from those given on direct examination for that year. Nevertheless, I think my conclusion was correct. These tables were prepared for presentation after I had given my testimony on direct.

Exhibits 33, 34 and 35 are intended to set forth the statements contained in water commissioners' reports. I do not consider these reports entirely reliable. It is the best information we have. Neither do I consider them quite unreliable. I consider them fairly reliable, except in the matter of acreage. Not absolutely, of course.

In my judgment as an engineer and a man of experience, it is necessary to take into consideration surrounding circumstances and conditions, aside from the mere demand of ditches on one particular day each week, in order to find out what the real average demands or necessities are. If such information is available, it should be used. I have taken the statements of the water commissioner as to what was needed to supply the demands or desires in his district on a particular day in each week. From that I have arrived at a conclusion as to what the average necessities were for that week or for the months taken by weeks.

Great variations in the necessities of ditches are caused by various things, like rainfall, variation in the flow of the river, etc. In considering these two years, with a knowledge of the relative demands in the different months, and taking four days in each week, I think that you would get a very fair average. It would be better, of course, if you knew what the actual demand was for each particular day; but we have not that, so we take what we have. Sometimes they are too large and sometimes they are too small, but on the whole I think they will average up fairly well.

Exhibit 35, sheet 2, deals with District No. 2 for the year 1912. On June 22nd the water commissioner's statement of demand is equivalent to a statement that all needs were supplied. As a rule the water commissioner states the demand in even hundreds. I did not consider the surrounding circumstances on June 22nd, as, for instance, the quantity of water entering District No. 2 from sources other than the flow of the river at Denver. The water commissioner reported such facts, but I did not investigate them. On that day he reported that there were 1,200 second feet entering the district from sources other than the Platte river at Denver. Adding that to the flow at Denver, there was nearly three times as much water in the district on that day as the canals required. My
625 exhibit does not mean that 700 second feet was actually the demand on the flow at Denver on that day, but that under any and all ordinary conditions that demand would be 700 second feet.

On the 20th the Highline in District No. 8 was carrying 250 second feet, which was probably not as much as it desired. There is on file in the State Engineer's office a permanent request from the Highline ditch that whenever water is available in the stream it be turned into their ditch to the full capacity. Therefore I consider that the unsatisfied demand of the Highline is represented by

the difference between the water running in the ditch and the full capacity of the ditch.

I cannot determine for them what the reasonable demand is. I must distribute water in accordance with the decrees. When the water commissioner states the last ditch that he is serving, I take it to be true that there is an unsupplied need in ditches not receiving water. With the data at hand and the variations we have had here in the distribution of water, we cannot reduce everything to an absolute mathematical certainty.

Exhibit 35, sheet 2, June 22nd. With accretions to the stream by inflow and seepage as reported by the water commissioner, the ditches above Clear Creek in District No. 2 would be the only ones which would not be supplied by such accretions. Those ditches are the Farmers and Gardeners and the Burlington. The Farmers and Gardeners is supplied by Denver sewage, leaving only the Burlington to be considered, and on June 22nd, notwithstanding the great flow in the river, the Burlington was drawing only 100 second feet. Possibly that flow was needed for Districts 1 and 64, but I did not investigate that question. The actual demand on the flow in the Platte River at Denver on June 22nd by District No. 2 was, therefore, 100 second feet, which was being used by the Burlington. Nevertheless I put down in my column of estimated demands 700 second feet, as representing the normal demand at that time of the month. Sometimes I consider the side notes in the water commissioners' reports. Do not remember whether I did so on that particular day. On that day water commissioner reports "Heavy general rains on Monday the 17th." Also, "Condition of district regarding irrigation, supplied." That indicated that the 100 second feet being drawn by the Burlington supplied their needs and desires.

In determining average needs and demands of ditches, it would be better to take a long series of years, but unfortunately we did not have the same complete data in the other years. I actually considered just the two years, 1912 and 1913. But the final results shown by me are not the average of those two years. 1912
626 was perhaps unfortunately selected by me. I found a great deal of difficulty in that year, by reason of the fact that there was a large surplus on many days. I do not think it entirely necessary to consider the conditions as they occur from year to year over a long period of years, before being in a position to say what ought to be true on the average. I think by a consideration of 1912 and 1913 we could determine what the approximate average demand was.

Exhibit 35, sheet 2, June 29th. According to the water commissioner's report there was no unsupplied demand, but I reduced his stated demand from 980 second feet to 700 second feet. Therefore, both on June 22nd and June 29th I have taken as the demand on the stream flow at Denver figures not justified by the facts as to either day.

On June 29th 500 second feet was being diverted by the canals for storage. If Barr Lake had then been supplied, the storage would then be under a right subsequent to Cheesman. Barr Lake

is usually filled in the winter, more particularly in September, October and November. They usually take the very first water available for storage. As a general rule, and almost invariably, Barr Lake's priority is filled before the irrigation season begins; therefore it is a fairly safe assumption that this 500 second feet being diverted on June 29th was under a storage decree subsequent to Cheesman.

I did not consider what the accretions to the river were below Denver on that date. It appears that the inflow from tributaries for the week ending June 29th was at the rate of 1800 second feet, and the accretion at the rate of 300 second feet. That was nearly three times the quantity of water used by the canals. Therefore it is probably true that there was no demand upon the flow of the Platte at Denver except to supply ditches above Clear Creek.

I did not investigate the demands in the districts below No. 2. There were nearly 1400 second feet passing from District No. 2 into District No. 1, and the average for the previous week had been over 2000 second feet. The only thing I had to consider at all was the demands of ditches above Clear Creek in District No. 2 as a demand upon the flow of the river as it passed Denver. The Burlington and the Farmers and Gardeners were fully supplied, therefore there was not any demand at all for District No. 2 upon the stream flow at Denver on that particular day. Nevertheless I put down an estimated demand of 700 second feet.

1912 was a year of satisfactory flow. The greatest diversions occur in the years of large flow, but not the greatest demands. The figures I put down on sheet 2 of Exhibit 35 do not represent my conclusions for the year 1912. Those conclusions represent
627 what in my judgment would be the demand in normal ordinary years. The figure put down by me for June 29th is what I considered under ordinary conditions would be the average demand for that time of the year, not the absolute figures for that particular day. These figures of mine, instead of being a deduction from the facts appearing on the particular day in 1912, represent a deduction of my own as to what the demand would be on the average, for the average year, and under average conditions. All of these figures are my judgment on the matter. That conclusion depends upon my judgment and experience, and on the examination of other records, particularly Exhibits 33 and 34 and the conclusions of Mr. Anderson and Mr. Comstock.

Exhibit 35, sheet 2, June 29th. As of that date the water commissioner's report has side notes as follows: "Weather for week has been, showers;" "condition regarding irrigation, fine." June, 1912 was unusual, and differed from the average month of June.

I have put down on the last sheet of Exhibit 35, which represents my final conclusions, none of the figures which I arrived at as shown and set forth on sheet 2 of Exhibit 35, which pertains to the year 1912. None of the conclusions which I put down on said sheet 2 in respect to the year 1912 has been carried into my final conclusion on the last sheet. The figures set down by me as my conclusions on sheet 4 of Exhibit 35 are the exact figures carried into

the final sheet, or final summation. Said sheet 4 relates to the year 1913, but they did not necessarily have to be for that year. Nevertheless the figures for 1912 affected my final conclusion.

In assuming that the flow of the stream at Denver at times when the ditches in District 2 are approximately supplied represents the demand of District 2 upon the Denver flow, and in assuming that the unsupplied demands of ditches in District No. 2 must be supplied in their entirety by water flowing past Denver, I have assumed that the other districts tributary to District No. 2, such as Districts 3, 4, 5, 6 and 7, were not improperly withholding water. I made some investigation respecting those ditches. I studied a tabulation which the division engineer had once made for use in connection with the demands of the Highline. This tabulation showed that nearly all of the ditches in all of these tributary districts were prior in point of time to Lake Cheesman, also prior in point of time to the Burlington. But I did not take up the consideration of diversions in the tributary districts with respect to the individual days when I was estimating the demands of District No. 2 upon the stream flow at Denver. If a ditch in a tributary
628 district is diverting water which is needed by a ditch in District No. 2 having an earlier priority, that water should be allowed to flow down into District No. 2. Therefore the mere fact that a certain ditch or ditches in District No. 2 are not getting all the water that I assumed they needed, does not necessarily indicate that that unsupplied need constitutes a demand upon the stream flow at Denver. It might be a demand upon Districts 3, 4, 5, 6 and 7. If a water commissioner in his report makes a demand for more water for his district, I regard that as conclusive evidence that there is an unsupplied demand for ditches prior in point of time to Lake Cheesman.

Exhibit 35, sheet 2, 1912, June 1st. According to the water commissioner's report there was an unsupplied demand of 173 second feet. Of this I have put down 5 second feet as the unsupplied demand on the stream flow at Denver, the total unsupplied demand being 173 feet. I do not know how much of this ought to have been supplied by the stream flow at Denver and how much ought to have been supplied by the inflow from tributary districts. That is one of the uncertainties—I do not know. The fact of the matter is that frequently, even though water is available, ditches do not draw it.

The Highline canal has an appropriation dating from 1879, which is three years later than the latest ditch drawing water in District No. 2 on June 1, 1912; nevertheless, the Highline on that date was drawing water at the rate of 500 second feet, had been drawing at the rate of 290 second feet in the preceding week, and continued to draw in large volume throughout the following month. As the rate of draft of the Highline was reduced, I assume that that reduction was by order of the Division Engineer, although I do not know. I did not examine the record of the action of the division engineer in that regard. However, I think it safe to assume that when a ditch is not drawing water it needs it, and therefore there is an unsupplied demand.

Exhibit 35, sheet 2, June 8. The water commissioner reports an unsupplied demand of 312 second feet. Of that I take only 15 second feet as the amount which ought to be supplied by the flow at Denver, in addition to what said flow actually supplied, and thereby arrive at 700 second feet as the demand of District No. 2 on the stream flow at Denver. I thought that 700 second feet would represent about the minimum of that demand. I might just as well have put down 685 second feet.

It appears from the water commissioner's reports that in District No. 2 at this time junior ditches were drawing water where senior ditches were not. It also appears that 322 second feet passed out of the district at the lower end. There were deficiencies in District No. 1, but I do not know whether they were in ditches prior
629 in point of time to Lake Cheesman. I do not know whether I investigated that question or not in respect to any of the shortages in District No. 1. I would not say that I had investigated it. Such shortages or deficiencies in District No. 1 could not affect the right to store in Lake Cheesman unless the ditches in question had decrees prior to that of Cheesman.

Exhibit 35, sheet 2, 1912, June 15th. The water commissioner reported a shortage of 395 second feet, which added to the stream flow at Denver made approximately 700 second feet. The latter figure also was my estimated demand for that day. But that is a mere coincidence. I would probably have arrived at the same conclusion though the water commissioner's figures had been different. I assumed that the demand is fairly uniform, and I used that figure in arriving at an average, although the amount which I added to the stream flow on this particular day was out of all proportion to the quantities added for other weeks in the same month, and although the relation of said added quantity to the deficit as reported by the water commissioner was out of all proportion to the relation of like additions made in some other weeks to the deficits as reported by the water commissioner. My purpose was to get a somewhat uniform demand for the month. On that particular day possibly a flow of 700 feet at Denver was not necessary, but in that period of the year, as shown by uses before and after that day, I concluded that 700 second feet for that week was justified.

On June 14, 1912, the last ditch drawing water in District No. 2 had a decree of 1885 and was drawing 20 second feet, and on June 17th it was drawing 100 second feet. On June 15th the water commissioner reported the last ditch drawing water in upper District 2 was of date July 8, 1876, getting 100 second feet, and in lower District 2 the last ditch getting water was of date 1874. Practically the same situation as on June 1st. It also appears that during all that time, practically from June 1st to June 15th, and later, the Highline ditch in District 8, with a decree dating from 1879, was drawing water at from 425 to 475 second feet. If the various ditches in District No. 2 with decrees prior to the Highline were actually needing water during that period, the Highline ought to have been shut down. But the fact that it was not does not necessarily indicate that said ditches were not needing water.

There seems to be a conflict between these two sets of reports of the water commissioners, There is also the element of time to be considered, and the fact that the water officials are not always able to regulate things as they should like to. One or the other, or both, sets of water commissioners' reports must be inaccurate. I
630 think the twice a week reports of the water commissioner are a little more accurate than his weekly report.

Exhibit 35, sheet 2, "See page in District 8." Taken from water commissioner's weekly reports. The figures given are an approximate average for the month. That column covers not only seepage, but also inflow as reported each week by the water commissioner. The figures here put down are the monthly averages of the water commissioner's weekly statements. It appears that the average for April is not the average of the water commissioner's weekly reports. I have forgotten how I arrived at that figure. It also appears that the figure put down in Exhibit 35 for May is not the average of the water commissioner's weekly reports. I cannot account for that. The same is true of June, July, August, September and October. I had an assistant in getting those averages, and I do not remember now just what was done.

The figures for seepage on sheet 2 of Exhibit 35, except for the month of September, when they agree with the averages of the water commissioner's returns, and except for the month of April, are all of them below the averages of the water commissioner's returns. I cannot say just how that happened. In my Exhibit 35 I undertook to deduct all of the seepage and inflow in District No. 8 from the demands of District No. 2 upon the stream flow at Denver. The water commissioners' statements as to seepage and inflow are largely estimates.

As to the flow in the main stream, I have taken the hydrographic records in the State Engineer's office instead of the water commissioners' reports, because I consider them more accurate.

The water commissioner in District 8 and the water commissioner in District 2 ought to read the gauge in the Platte river at Denver in approximately the same way. One, though, might read it at one time of the day and the other at another time, which would make some difference. As a matter of fact, it is probably true that the commissioner of District 8 does not read the gauge at Denver as often as the commissioner of District 2. I am afraid the water commissioner sometimes reports these stream flows without reading the gauge. I would say he roughly estimates it.

These water commissioners do try to favor their own districts. Like members of Congress, they try to get as large appropriations as they can for their respective districts. Each man's particular interest is in his own district, and he works for the interest of his own district. He is a local man, appointed out of a list of men presented by the boards of county commissioners in his district.

631 The action of the division engineer upon the conflicting claims of the commissioners of the various districts would indicate how much of unsupplied demand, if any, of District No. 2, for example, ought to be supplied by the sending down of more

water from District No. 8, or by the sending down of more water from the other districts, which are tributaries to District No. 2. The division engineer determines the amount which each must contribute.

There are wide discrepancies between the statements of the commissioners of Districts 8 and 2 concerning the outflow from 8 and the inflow from 2, although it is the statutory duty of those commissioners to report such fact, and although their determinations ought to be exact, because they depend upon the reading of the same gauge here at Denver. (The attention of the witness is called to many such discrepancies.) These discrepancies are accounted for, of course, by the desire of each commissioner to favor his own district, and also the commissioner of District No. 8 is more inclined to guess at what the gauge is going to read by observing the flow above, and then he thinks it ought to be about so much. (The attention of the witness is called to other discrepancies of like character.)

These figures show that the water commissioners' reports of flow in the main stream are not as reliable as the hydrographic reports. Their duties are such that very often they cannot visit the gauge just when they want to or just when they should. I should say that the water commissioners' estimates of flow in the main stream, where they have a gauge to read, would be more accurate than their estimates of the flow from tributaries and of seepage, which are purely estimates, without gauges to guide them.

As to the estimate of seepage, the water commissioner arrives at that by an arithmetical process, as follows: From the total amount distributed to the ditches in his district, plus the total flow out of his district he deducts the amount of the inflow on the main stream, and this gives him the amount of accretions in his district from tributary inflow and seepage. To make this result accurate he must know accurately what is coming into his district and what is going out of his district. He must either gauge or estimate the inflow of the tributaries. There are no gauges on any of the streams tributary to Districts 8 and 2. The estimates of the water commissioners are the best information we have as to that. The water commissioners guess at the amount of the tributary inflow. As to seepage inflow, they have still less data to guide them.

As to Exhibits 33, 34 and 35, the data which they include was obtained as follows: As to stream flows, from State Engi-
632 neer's hydrographic records; as to quantities of water diverted by canals, from water commissioners' weekly reports; as to quantity of water so diverted which consisted of stored or reservoir water, also from water commissioner's weekly reports; as to quantity of water so diverted for purposes of storage, also from water commissioners' weekly reports; as to seepage and return flow, also from water commissioners' weekly reports; as to demands of the ditches, also from water commissioners' weekly reports. I took the State Engineer's hydrographic records for stream flows, instead of water commissioners' reports, because I thought them more accurate. There is no reason to believe that the water commissioners' statements as to stream flow are less entitled to credence than their statements

as to seepage and inflow, but I took the water commissioners' statements as to seepage and inflow because I had to in our hurry to make the record.

As to the demands of ditches listed by the water commissioner in his reports, if a ditch requests a certain quantity of water, and if that quantity of water were less than the quantity decreed to that ditch, such a request would undoubtedly have an effect upon the quantity which the water commissioner would set down as the demand of his district. I do not know just what influence those requests have on the water commissioner's statements of demand as made in his reports.

As to the water being actually diverted by ditches, the water commissioner depends to some extent on the statements of the ditch people themselves. But it is the practice of nearly all water commissioners and their deputies to have what they call private marks on ditches, which they can observe as they pass along. That is not a very accurate method of determining the flow in a ditch. It would be an estimate only.

As to diversions, all that the information tabulated in Exhibit 35 shows is simply the total amount being diverted, and it is impossible to tell what ditches were diverting the water and how much is being diverted by the individual ditches.

In Exhibit 35, table 2, the figures which I have put down under the column "Estimated Demand" were figures I had in mind as to what probably would be true in the average year, without regard to the particular facts as shown for that particular year, or rather for that particular day, upon the water commissioners' reports. I did not investigate to determine what action the division engineer had taken in respect to the demands of the various water commissioners, or in respect to the distribution of water in view of those demands.

Exhibit 35, sheet 4, relates to both District 2 and District 8 for the year 1913. So far as it relates to District 8, it sets forth
633 the same data appearing upon Exhibit 35, sheet 3. (The two sheets here explained.)

Exhibit 35, sheet 3, figures designated "Average Assumed," represent the amount necessary to flow at the canon in the average year to supply the needs of District 8. These amounts do not correspond with those entered in respect to District 8 on the final sheet of Exhibit 35. That is because I was treating the matter in a different way.

The figures on the last sheet of Exhibit 35 pertaining to District No. 8 also include the Water Company's diversions.

As to the average assumed for August on sheet No. 3, the difference between that and the figure on the last sheet of Exhibit 35 is due to the fact that in my original testimony I used 545 for that month, and felt it necessary to put it down in the exhibit. 545 was the average flow at the canon.

The figures pertaining to District 8 on the last sheet of Exhibit 35 include the 65 feet as the constant demand of the Water Company for its direct flow rights, but those on sheet 3 do not, nevertheless the figures on sheet 3 are higher than those on the final sheet.

Exhibit 35, sheet 4. On this sheet there is assembled information relative to both districts for the year 1913.

Statements on sheet 4 of Exhibit 35 compared with statements in Exhibit 33 and 34, with other statements in the water commissioners' reports, and with the record of diversions of the Highline ditch.

As to June 7, 1913, Exhibit 33 states that the latest ditch drawing water in District No. 8 was 1873, and on June 16th 1868; and in District No. 2, 1877 and 1876. Comparing those with the statements on sheet 4, Exhibit 35, it appears either that there is something wrong about the tabulations made by me, or that there is something wrong about the water commissioners' reports from which the tabulations were made. Sometimes the early priorities do not demand water when the later priorities are getting it. The mere fact that a ditch is not at any particular time drawing water, or is drawing only a part of its priority, does not necessarily indicate that it needs that portion of it which it is not drawing.

Exhibit 35, sheet 4, portion relating to District 2, month of June. To the average flow at Denver, 666 second feet, I added 34 second feet, making a total of 700 second feet, and then deducted 106 second feet, which I designate as seepage; that stands for seepage in District No. 8. In arriving at the average flow at Denver I took the average of the first, second and fourth figures in that column, omitting the third figure relating to the flow on June 21st. The figure which I took is not even the average of these. I took
634 666, the average being 663, but if I had taken 633 I would have added 37. I resired to reach the round number 700.

When the Burlington does not draw in the month of June, I assume that there is an unsupplied demand on that account of 150 second feet. I use a certain amount of judgment and reason. In this case 34 second feet is the extent of my judgment and reason as to the unsupplied demands which ought to be supplied out of the flow at Denver. While the unsupplied demand as reported by the water commissioner was greater than this, I did not undertake to apportion it between the flow at Denver and the tributary inflow. I simply said this: that there should have been something more than the average amount flowing past Denver, and the nearest even figure, and the even hundreds of second feet, was 700.

It is not necessary to determine the average flow of the stream past Denver, although we are trying to determine the average of the unsupplied demand which ought to be supplied from that source.

As to the month of June, 1913, the real conclusion I came to was that there ought to be more than 666 second feet flowing in the river past Denver, therefore I added 34 to make an even 700. I took what I considered to be the minimum that I could see was necessary, and called it 700. What I really did was to determine, by some means or other, that 700 was the quantity that ought to be flowing past Denver. Then I added 34 to 666, so that it made an even 700, as a matter of arithmetic. 34 simply represents a figure that I took in order to bring the result to 700, and my conclusion would have been to the same whether the Burlington on June 7th

had been drawing water at the rate of 100 second feet or whether it had not.

Exhibit 35, sheet 4, month of July. To the average of the stream flow at Denver I added the arbitrary figure 68, to bring the total up to 700. That addition was made upon the same principle and for the same purpose as the addition of 34 in the month of June.

There were unsupplied demands on July 19th, notwithstanding a flow in the river of 1115 second feet, although in the following week, with a much less flow in the river, the Burlington ditch, with a priority of 1885, was drawing to the full extent of its desire. I concluded that there was an unsatisfied demand on July 19th, merely because ditches after 1876 were not drawing on that day.

On July 17th and July 21st there were unsupplied demands in District No. 1, but I do not know whether any of these were by ditches prior in point of time to Lake Cheesman; nor did I
635 investigate whether that unsupplied demand would be re-reflected back to the canon.

As to July 9th, the report of the water commissioner in District No. 2 says: "Used by ditches for irrigation, 1400 second feet," also "Total amount of water necessary to supply the present needs is 1400 second feet." Although I think the fact that the Burlington was not drawing water was sufficient to indicate unsupplied demands, I would be inclined to take the water commissioner's report to the effect that there was no more water needed.

All of these computations which I have made in respect to demands on the flow of the river at Denver, and in respect to demands on the flow of the river at Platte Canon, are arrived at by similar methods to those which I have now described. The figures thus arrived at, as shown upon sheet 4 of Exhibit 35, are the ones which I have carried forward to the final sheet of Exhibit 35. The individual figures entered on that final sheet, as regards the respective districts, are the conclusions expressed on sheet 4 of the exhibit, of the demand of each of these districts on the canon, which conclusions are also influenced by the other sheets in the exhibit. After adding up the figures for the two districts, I made a deduction therefrom. I wanted to be sure that the figure was not excessive, and also I wanted to deal with round figures rather than exact figures. Some of them I did not reduce at all, and others I reduced, not by percentages, but by absolute amounts. The ratio of reduction differed quite widely for different months. In the large months it was my purpose to arrive at the nearest thousand, in the small months the nearest hundred. I exercised my judgment. The final amount represents my final and best judgment.

In the month of August 545 was set down by me because I had mentioned it in direct examination. As a matter of fact, that, instead of being my estimate of demand in District No. 8 for that month, was my statement of the stream flow. Nevertheless, I set it down and made a deduction sufficient in quantity to reduce the total for the month of August to 700.

I have now explained as fully as I can the method by which I arrived at my determination of the quantity of water which must

have been flowing at Platte canon in each month; that is to say, the rate at which it must be flowing, before Cheesman could store, and the quantities assumed by me for that purpose in preparing my Exhibit 30 are those set down on the last page of Exhibit 35 after the words "Final Amount."

636 (Figures quoted from water commissioners' and division engineer's reports as to acreage, diversions and demands in District No. 2 for the years 1911 and 1912.)

The duty of water from the irrigation works, such as reservoirs and ditches, is considerably affected by weather conditions—that is, rainfall—in a particular year. The rainfall in 1912 from April to October amounted to 15.01 inches, being about 25% above normal. Such rainfall means an addition of 1¼ acre feet per acre to the amount supplied by the ditches. The rainfall in the months of April to October, 1913, was apparently less than normal.

As to duty of water for lands in the vicinity of Denver, I think probably 2½ acre feet per acre per annum would be all right.

I am the author of United States Department of Agriculture Bulletin No. 118, entitled "Irrigation from the Big Thompson River." In that I gave a tabulation of the use of water from The Big Thompson River for 1901, showing a duty of water there of 1.91 acre feet per acre per annum, including reservoir water. In that article I said: "The duty of water, it will be noticed, in the district is 187 acres per cubic foot per second, running 180 days, and the land was covered to an average depth of 1.9 feet." In my testimony here about the City Ditch, I said that a second foot would irrigate about 38.4 acres. In that same article I said: "The possession of an old and abundant water right does not convey the right to use the privilege wastefully and to the harm of others less fortunate. In practice, however, it is impossible to prevent this abuse, which is illegal and to be condemned." I am still of the same opinion. But I do not think you could prevent the use of water unless it is really a waste. The courts have determined that for you, as I said before, and these are legal vested rights that must be respected. In that article, in support of the paragraph last mentioned, I cited Session Laws of Colorado, 1895, page 197. That statute prohibits not only the waste of water, but also a wasteful or extravagant use of it by the consumers.

In Exhibit 35, on the last page, I have set down the total quantity of second feet which must each month be passing Platte Canon before storage is to be allowed at Lake Cheesman. That is the quantity of so-called original water, originating at and above Platte Canon, necessary to supply these prior direct irrigation rights. Flowing at the specified rates, those requirements would produce in the months of April to October, inclusive, 248,000 acre feet. Deducting from that the 28,000 acre feet that goes to supply the Water Company's direct flow rights, leaves 220,000 acre feet of original water

637 proceeding from the canon for the irrigation of 103,000 acres, to-wit, 27,000 in District 8 and 76,000 in District 2, which is 2.13 acre feet per acre of so-called original water. My testimony in the Wyoming-Colorado case in respect to the duty of original water

in the Poudre valley was .9 of one acre foot per acre. That is the same method I employed in the Wyoming case, except that I deducted the amount flowing out of the district. The Platte is a natural stream, comes out of the same mountains as the Poudre, passes over the same kind of country, but has more tributaries than the Poudre. The more tributary streams there are, the more additional water comes in for use, in addition to that which originates at the canon.

The acreage in District No. 3 is 265,000. The actual flow out of Poudre canon is in acre feet 320,000; making a duty there of so-called original water of 1.2 acre feet per acre, assuming that all of it is applied in District No. 3. In that district there are no tributaries of any moment, while in Districts 2 and 8 there are important tributaries.

As to Exhibit 30, showing my estimate of possible storages at Lake Cheesman, on the assumption that the demands at Platte Canon are to be satisfied before any storage can occur, are such as indicated on the last sheet of Exhibit 35.

1902, February. No records of stream flow at South Platte for that month. Flow estimated by an inspection of flow at Cheesman. Assumed flow in North Fork to be low because it was low in South Fork. The North Fork supplies perhaps 55% and the South Fork 45% of the total discharge, but there is no regularity in the relation between the respective flows for the two forks month by month, and there is a wider discrepancy in the winter months. March, November and December estimated in the same way, there being no record of stream flows.

1903, January and February estimated in the same way. It is necessary to know what the flow in the main stream was in order to say positively that there could not be any storage in Cheesman in those months. Possibly I was influenced some by the fact that Cheesman in that month turned out a greater amount of water than was coming in. But they may have turned it out to keep the channel open. And I do not know whether their actual needs for city supply were greater or less than 66 second feet.

For purposes of comparison with the estimates of Mr. Anderson and Mr. Comstock, the amounts necessary to supply the Platte Canon Ditch should be treated in the same manner as they have dealt with them during the winter months.

In May, 1903, I allowed no storage, although storage actually occurred at an average rate of flow of 13 second feet, as appears
638 by Exhibit 31. I do not account for that actual storage, but under the assumptions I have made it should not have occurred. That was eleven years ago, and the requirements might not have been the same. Moreover, we are dealing with averages, and the average assumed by me covering the demands for that month may have been too high, as applied to that particular year.

Exhibit 35, sheet 2, Seepage. Figures were obtained by taking the report of the water commissioner as to the average seepage for the preceding week, not the seepage for the particular day, and thus averages were obtained.

Exhibit 30, 1903, December. The amount withdrawn from the reservoir in that month increased the stream flow, and was probably sufficient to offset any possible storages when the actual stream flow exceeded 66 second feet.

Exhibit 30, 1904, May. I allow the quantity actually stored, although the average flow at Platte Canon was 470 second feet, being less than the 500 second feet required by me. There were, however, days when the stream flow exceeded my requirements. Moreover, the quantity actually stored, if it had been allowed to flow down, would have increased the stream flow. Those circumstances possibly justified taking what was actually stored.

June, 1904. No storage allowed. My requirements at Platte canon 1000 second feet. There was actually stored at Lake Cheesman in that month 17,406 acre feet. If that had flowed down, instead of being stopped at Cheesman, it would have increased the stream flow. In that month the average flow at Platte canon was 541 second feet. There was a maximum flow approaching within 2 or 3 second feet of my requirement. If the amount detained at Cheesman had been allowed to flow down, the flow at Platte canon might have been increased on those days above my requirements, but the stream flows in June are fairly regular.

Ditch diversions are not greatly affected by rainfall, unless the rain be continuous for two or three days. I do not know what the average rainfall was in the month of May, 1904. If the rainfall was 3.24 inches it would have affected the demand of the ditches somewhat.

Notwithstanding the storage actually made and the rainfall, I believe there was no possible storage for Lake Cheesman in the month of June, 1904, upon my assumptions as to demand. The fact that Cheesman actually stored that quantity in that month does not indicate that my estimate of demand is too high. My requirement of 1000 second feet for June would produce 60,000 acre feet in
639 that month. Only 32,400 acre feet passed Platte canon in June, 1904. Under the peculiar circumstances in that particular year Lake Cheesman might have been permitted to store the quantity which it did store, even though my requirement is correct. The farmers and irrigators below were then watching, and have since watched, Lake Cheesman carefully.

By taking this Exhibit 30 and examining it month by month you will find, of course, that in some months I have allowed too much storage, and in others I have allowed too litle, but adopting the general rule of 1000 cubic feet per second as the necessities for June, I think we have shown that that was the necessity.

I examined the exhibits of Anderson and Comstock month by month, deducting therefrom when according to my estimates I thought there should not have been storage at Lake Cheesman, but adding nothing when according to my estimates and assumptions storage might have occurred in greater quantities than as specified by them. But if there was anything to add, it would be small.

Exhibit 30, 1904, July. I did not allow the storage which had actually been made of 22,672 acre feet. That storage was made at an

average rate of 36 second feet, on an average stream flow at Platte canon of only 431 second feet, and a maximum of only 1407 second feet on one day in the month. As to November and December, additions should be made to my estimates, or deductions from those of Anderson and Comstock for purposes of comparison, because of the different method of treating the requirement of the Platte Canon ditch.

Exhibit 30, 1906, April. The figure for April 25th should be 270 instead of 210. (Attention called to other errors, which witness will check and correct.)

Exhibit 30, 1907, November. No storage estimated, although the stream flow at South Platte, as shown by the records, greatly exceeded my requirement of 66 second feet. It is possible that I ought to have allowed it.

August, 1908. No storage allowed. If on August 6th the recorded stream flow at Platte canon was 740 second feet there ought to have been storage allowed.

Exhibit 30, 1910. Adding to my estimate the quantities resulting from the difference in the treatment of the Platte Canon ditch, would bring my total for the year to 49,480 acre feet, as compared with Anderson's estimate of 50,000 acre feet.

Exhibit 30, 1911, July. No storage estimated. If the records of stream flows show on certain days excesses over my requirement of 1000 second feet, I cannot say how I happened to overlook it. If the statements of stream flows as assumed in the question are cor-
640 rect, it would result in a possible storage in that month of about 5200 acre feet. I do not remember whether there was any actual storage in Lake Cheesman in July, 1911. In presenting Exhibit 31, showing actual storages at Lake Cheesman, I detached the sheet relating to the years 1910, 1911 and 1912. I have this other sheet with me, and from it there appears to have been actual storage made in Lake Cheesman in June and July, 1911. I do not think those actual storages should be included in my Exhibit 30, because that was a month when there was objection to Cheesman's having stored, and they turned the water out later. But if the stream flows were indicated in counsel's question, the addition of 5210 acre feet at least should be made to my estimate for July, 1911. In June, 1911, there was an actual storage in Lake Cheesman of about 4912 acre feet, making a total for June (4912) and July (6430) of 11,342 acre feet.

Although the records of the Water Company disclose actual storage in August, 1911, I do not think it ought to be allowed.

In October, 1911, there was an actual storage made in excess of the amount allowed in Exhibit 30. I do not think that ought to be included in the exhibit, although it was made and permitted, when the minimum flow at South Platte for that month was 92 second feet, the maximum 320 second feet and the average 144 second feet, to a total quantity of 2174 acre feet. That does not indicate that my requirement is too high for the month of October. The fact that Antero in that month of October stored 4500 acre feet makes no

difference. Water may have been turned out to satisfy demands below.

I do not mean to say that when there has been a large flow in the river in one month, or in certain weeks or on certain days in the month, which permitted storage and storage has been made, that because subsequently the river falls or the demands of the ditches increase, and therefore the stored water is used for the purpose of satisfying such demands, that those facts indicate that the storage could not have been made when it was made.

The withdrawals from a reservoir do not necessarily indicate unsatisfied demands of ditches below which would limit the right to store.

Exhibit 30, 1912, April. I estimate a possible storage of 4884 acre feet. There was in that month an actual storage of 7500 acre feet. The fact that the actual flows at Platte canon during the time that storage was accomplished were less than my average requirement does not indicate that my average requirement is too high. If the storage had not been made the stream flows would have been
641 increased. They were storing at Cheesman at a considerably greater rate than I say they had any right to do. If it be true that the records show actual storage in reservoirs in District No. 2 in April, 1912, of 6370 acre feet, I can only say that this Exhibit 30 represents the amount that could be stored in Lake Cheesman under certain assumptions. There are variations. Sometimes the demand falls below my average assumption, and on those days or in those months you can pick out cases where there is an apparent conflict. On other days I have allowed storage when as a matter of fact none could have occurred, and those things balance one another.

1912 is one of the years upon which I base my conclusions as to demand, but as I have stated, my examination of 1912 was unsatisfactory, and I did not use 1912 to the same extent that I did 1913 in making my estimates of demands and requirements of ditches.

Exhibit 30, 1912, May. There were actual storages in Lake Cheesman in that month greater in quantity than allowed by me. It is probable that those storages occurred constantly, and every day in the month. Even though it appears that those storages were made when the flow at Platte Canon was less than my requirement; though on May 11th the water commissioner of District No. 2 reported that "All reservoirs may store, as far as this district is concerned. Heavy rains, general," and although there was actually stored in District No. 2 in that month of May, 1912, 10,500 acre feet, and in Antero 1800 acre feet, in addition to what was stored in Lake Cheesman, I do not think that indicates that my estimate of requirements of ditches was too high, because, as stated before, that estimate was of an average, and not of the requirements of any particular day, or in any particular year.

As to June, 1912, the same is true, although in that month actual storage was made in Cheesman to the amount of 6900 acre feet, on days when the flow at South Platte was less than my requirements, and although in that month there was stored in District No. 2, 9290 acre feet, and in the Antero 10,200 acre feet.

Exhibit 30, 1912, August. Total should read 9694, instead of 8694.

October, 1912. I allowed 368 acre feet. More than that was actually stored. Although, in addition to what was actually stored in Cheesman, there was in that month 23,380 acre feet stored in District No. 2, nevertheless I do not think my estimate of average demand for that month is too high. 1912 was a year of very considerable precipitation, and the demand in that particular
642 year, of course, was less. Moreover, they had used a large quantity of water in the earlier months.

Exhibit 30, 1913. That is the other year upon which I based my reasoning and my conclusions as to the demand at Platte Canon. As to April, 1913, although in the first thirteen days of the month there was an actual storage at Lake Cheesman of much more than I estimated, yet my requirement for April is the average demand for the month, and the demand actually increases from the first of April on to the first of July. My estimate of requirements may be too much for the first part of April, but if so it would be too small for the latter part of the month. It is impossible to get day by day averages for the demand or requirements, because we have only weekly, or at best bi-weekly, reports from the commissioners. Such conclusions as these relative to the average requirements of ditches are not susceptible of absolutely accurate mathematical calculation. It is and must be a generalization. The data at hand must be examined with judgment, and you must apply your reason to it, and you must apply your experience.

Exhibit 30, 1913, May. Even though there was stored in District No. 2 4200 acre feet, in addition to what Cheesman actually stored, that does not indicate to my mind that my estimate of storage is too low.

October, 1913. Although in that month of October there was actually stored in District No. 2, 17,080 acre feet, and those storages were on priorities subsequent to Cheesman, that does not indicate that Cheesman might have stored all the water that was flowing in the South fork of the South Platte.

Notwithstanding all of the matters to which my attention has been called, and notwithstanding I require flows at Platte Canon which in the aggregate would furnish 220,000 acre feet at Platte Canon of so-called original water, for the irrigation of 103,000 acres, a duty of original water of 2.13 acre feet per acre, and although in the Poudre Valley, under similar circumstances, the duty of orig-nal water was found by me to be less than one acre foot per acre, nevertheless I do not think that my estimates of requirements or demands of ditches below is excessive. And this is true even though in my monograph on the Big Thompson I stated that the average use of water—that is, the average duty of the entire water supply, not the original water supply—was 1.9 acre feet per acre.

(Quotations from witness's monograph or bulletin on the Big Thompson read and admitted.)

(Exhibit A-65, transcript of testimony of John E. Field in suit of

Wyoming vs. Colorado, marked and submitted to witness for identification.)

643 My procedure in this case was as follows: First, estimated rate of flow which must exist at Platte Canon in each month in order to entitle Lake Cheesman to store at all, that estimate being set forth on the last page of Exhibit 35; second, on the basis of the foregoing assumption, estimated possible storages year by year for Lake Cheesman, shown for the years 1902 to 1913 inclusive in Exhibit 30; third, taking possible storages thus estimated, and treating Cheesman as a reservoir for irrigation purposes, then assumed annual draft of 40,000 acre feet to show the operating results, the same being set forth in Exhibit No. 32.

Exhibit 32—1905. By arithmetical error, final amount is 1000 acre feet too little. This should be corrected and the correction carried forward to April, 1906.

Exhibit 32—1906, May. Amount in reservoir should be increased by 3000 acre feet, including addition for previous errors. June. Amount in reservoir should be increased by 4000 acre feet, including addition for previous errors.

Exhibit 32—1907, March. Amount in reservoir ought to be increased by 14,000 acre feet, including previous errors.

Exhibit 32—1909. No figures for this year, because undoubtedly the reservoir could have furnished the estimated draft of 40,000 acre feet and yet have been full at the beginning of the next year.

Exhibit 32—1910, June. Amount in reservoir should be 69,064.

Exhibit 32—1911, January. Amount in reservoir should be 48,542. 1911, July. If recorded river flows in that month exceeded my requirements sufficiently to permit storage of 5210 acre feet at Lake Cheesman, that amount should be entered here; I have not checked the recorded flows.

Exhibit 32—1912, August. Possible storage should be 9694 acre feet. That correction, adding 1000 acre feet, should be carried from that point on through the rest of the exhibit.

Exhibit 32—1913, September. Possible storage should be 10,648 acre feet.

Evaporation, as treated in Exhibit 32. The deduction each year of 3000 acre feet for evaporation was without any regard to the quantity of water in the reservoir in that particular year, and was merely an average deduction, based on an estimate of the average exposed area. The exposed surface varies with the height of the reservoir, and that makes a very great difference in the amount of evaporation. I calculated the average exposed area for each month, then calculated the average for each year, and so obtained the average for the period. I have given no credit for the fact that when the reservoir is full, the appropriation has not been exhausted,

644 and water is available for storage, losses from evaporation may be made up out of the stream flow. The quantities I have considered for the purpose of ascertaining the exposed area are the quantities in the reservoir at the end of each month. During the month the reservoir rises and falls, making a difference in the exposed area. The average exposed area for each year was as follows:

1902, 672 acres; 1903, 450 acres; 1904, 179 acres; 1905, 482 acres; 1906, 623 acres; 1907, 820 acres; 1908, 712 acres; 1909, 874 acres; 1910, 718 acres; 1911, 504 acres; 1912, 513 acres; 1913, 675 acres. After that I obtained my grand average by adding up all of the months and averaging it. In arriving at my average annual loss of 3000 acre feet, I considered that there is a certain amount wasted from the reservoir for power purposes, lighting, etc., and that there is a certain amount of loss from seepage—not large I presume, but nevertheless something. All of these things are included. About 2700 or 2800 acre feet covers the evaporation.

As to the rate of evaporation, it makes some difference as what time of the year the large exposures of surface occur. I consider it entirely fair to determine an average by such a method as this and then make that deduction, even in the years when there is little if any water in the reservoir and at times when the storage is low. I consider this to be so, even though in the year 1904, for example, there was no water in the reservoir in July, August, September and October, and although in that year there was little opportunity to refill because of low stream flow. In years of large flow and full reservoir the actual evaporation is greater, because of the greater exposed surface; but the opportunity to replace the loss by evaporation is also greater, because the water is in the river and Lake Cheesman is entitled to store it. Nevertheless in such years I deduct only the average for the whole period of years, and not the actual evaporation for that particular year. Then in the lean years, when there was little water in the reservoir and slight actual evaporation in consequence, and also a low flow in the river so that it was impossible for the reservoir to replace what had been deducted for evaporation, I nevertheless deducted the average quantity for the entire period of years. I admit that that is not as accurate a method as taking the evaporation month by month.

In preparing my Exhibits 30 and 32 I made use of Mr. Comstock's tables of stream flow, corrected for Lake Cheesman storage, from about the middle of 1908. I understand that Mr. Comstock determined the storage at Cheesman by taking the difference between the inflow and the outflow as recorded. The inflow and
645 outflow from Cheesman, as a matter of fact, is gotten by surveying the height of the water in the reservoir. They did not go up there and measure that inflow and outflow every day. That automatically takes care of evaporation. Cheesman is not charged with it, which it should be. They have wasted some water there and made no account of it. They have constantly refilled the amount that has been evaporated—"given us the worst of it, in other words, all along the line." I said that the way they computed and determined the amount of water which had flowed into Lake Cheesman was by the changes in lake level, and I do not wish to depart from that statement. Thereby they have taken care of evaporation, because, instead of measuring and stating the quantity which actually flowed in, they have simply stated the change in the level of the reservoir. The quantity thus determined is the quantity which actually flowed in, less the evaporation which may have occurred. Nevertheless, I do not think that in using Comstock's figures for corrected

stream flow the actual evaporation at Lake Cheesman has been taken care of.

I do not think I have twice deducted for evaporation. I do not think that is the effect of it. I do not know that I can explain just now why not; I would like to think it over awhile.

By that method he simply accounted for the net; he has not accounted for the gross. You should take what is in the reservoir and then estimate your losses by seepage and evaporation and add it to the quantity. You would get a greater quantity.

In Exhibit 32 I took 40,000 acre feet as the basis of my annual draft because it happened to be a round number very largely, and also I could estimate that there would probably be a shortage in 1904 with that draft. 40,000 acre feet was not the largest figure that I experimented with. I roughly checked up with 50,000.

(The attention of the witness is called to the great quantities left in the reservoir at the end of each year, and the amounts wasted on assumed draft of 40,000 acre feet as shown by Exhibit 32.)

In view of these enormous percentages I could have made a draft of more than 40,000 acre feet, but if you did you would have less than your 40,000 acre feet in 1902. 1902 was an exceedingly unusual year in respect to the flow in the river. Without having the records before me, I cannot say whether it was the driest year in the history of the river.

By assuring an absolutely guaranteed supply you get a larger price for your water. As your guarantee is less you get a less price. It can be figured out where the point is that the quantity mul-
646 tiplied by the price will give the highest revenue. That is the proper place to put your annual draft. A lack of supply once in fifteen years would not affect the price a great deal, nor would a lack of supply twice in fifteen years. A lack of supply three times in fifteen years would affect the price quite considerably; I would not say how much. Assuming that the water is worth $50 an acre foot, with one shortage in twelve years, as shown on Exhibit 32, that price would not be lessened by $10 an acre foot if there were two shortages in fifteen years.

I made three reports to the former board of appraisers appointed in 1907, the first in December, 1907, the second dated January 20, 1908, and the third somewhat later. I have with me the volumes which contain my estimates and conclusions in respect to Lake Cheesman as of those dates. I then went through a somewhat similar process of determining possible storage at Lake Cheesman and gave that conclusion as to what it was. As a part of that report I presented tables upon an assumed annual draft of 45,000 acre feet. Thereupon I said, in substance, in that report (exact quotation in original transcript) that 45,000 acre feet could not be stored each year, although we are justified in taking a certain amount of risk of shortage and of occasionally asking the farmers to do with a little less than the average amount. And I further stated in that report that the maximum average which we are justified in selling is 40,000 acre feet per annum.

In that case I pursued a somewhat similar process to that pursued here; determined what I considered to be the average flow necessary

at Platte Canon before storage could be made at Lake Cheesman, in the irrigation season, and arrived at the same result here testified to, to-wit, a draft of 40,000 acre feet per annum, although upon different assumptions as to demand upon the canon. At that time I applied to said 40,000 acre feet a unit price of $40 per acre foot for supplemental supply, making a total for Lake Cheesman, as a water producing entity, of $1,600,000. At this time my unit price per acre foot for a supplemental supply is $50. Water rights have advanced in value since 1907. I have taken that into account in assigning my new price. I now testify that the value is $50 per acre foot if the water is used in July, August, September and October.

After reporting to the old board of appraisers I made no subsequent investigation of these water rights until I began to investigate for the purpose of testifying in this case. My subsequent investigations have disclosed no reason for changing my opinion as to the available quantity of water previously expressed.

647 My last report to the board of appraisers was some time in February, 1908. My conclusion was a possible storage in Lake Cheesman on the average of not to exceed 40,000 acre feet, with stream flows required at Platte Canon before any storage be permitted of the quantities specified in that report. These were the amounts estimated to be necessary to supply prior rights.

Under date of April 24, 1908, I wrote for and delivered to Mr. William E. Bates, a report entitled "Report on Storage Possibilities, South Platte River, Highline, Eagle Rock and Two Forks Reservoir Sites." Exhibit A-66 is a copy of that report. In that report I considered the water available for storage in those three reservoirs. All three of them are below Lake Cheesman. The Two Forks Reservoir is on the South Platte River below the junction of the north and south forks. The other two, the Eagle Rock and the Highline, are on the south fork of the South Platte, above the Two Forks but below Lake Cheesman. They were and are merely projected reservoirs, and have not yet been constructed.

In my report to the board of appraisers, given in February, 1908, I stated, speaking of Lake Cheesman: "We find that the maximum average which we are justified in selling is 40,000 acre feet per annum. * * * It may seem surprising that this famous reservoir's value for irrigation purposes is not in excess of its cost. * * * It has been shown in the discussion of Lake Cheesman rights that little, if any, water is available for storage on the south fork after 40,000 acre feet per year have been furnished from that reservoir, hence in further discussion of storage possibilities on the South Platte river only possible storage sites which derive their supply from the north fork will be considered. * * * From an investigation of the records of discharge of the South Platte at Deansbury, it is seen that there is available for storage purposes, after all demands of prior rights in Districts 2 and 8 have been satisfied, an average amount of approximately 16,000 acre feet per annum, which is about one-third the total storage capacity of Lake Cheesman." Deansbury is below the junction of the north and south forks, on the main stream.

In the Bates report (Exhibit A-66), on April 24, 1908, I said in substance, that we might assert with considerable confidence that a

reservoir deriving its supply from the north fork as large as Cheesman Lake was justified, and "from a study of Cheesman Lake and the run-off of the south fork, we feel justified in stating that an increase in the capacity of that reservoir is justified. The capacity of Cheesman Lake is about 80,000 acre feet, and its justified increase capacity may be sufficient to raise it to 100,000 acre feet capacity."

648 Such an increase might be justified in order to carry over water from such years as 1900 into such years as 1903 and 1904.

On my assumed draft of 40,000 acre feet, as shown by Exhibit 32, water went over the spillway in 1902, because we began that year with a full reservoir; also in 1907, 1909 and 1910, in certain months of each year.

In the Bates report (Exhibit A-66) I said, in April, 1908: "I am of the opinion that a reservoir of 80,000 acre feet is justified, on account of the north fork supply alone, and 20,000 acre feet on account of the south fork supply, or a total of 100,000 acre feet, but that beyond these figures the advisability is questionable." I had previously stated in my report to the board of appraisers, about 60 days before, that "There is available from the north fork for storage purposes, after all demands of prior rights in Districts 2 and 8 have been satisfied, an average amount of approximately 16,000 acre feet per annum." If 80,000 acre feet was justified, 16,000 certainly was. Of course I made still further investigations for the Bates report. I cannot say now just what I had in mind when I said 16,000 was the limit.

I also reported to the board of appraisers that the safe deliverable storage for Lake Cheesman was 40,000 acre feet. In that connection I submitted tables of possible storage covering the years 1900 to 1904, in only one of which, 1900, had I found a possible storage up to the capacity of the reservoir. I had also found and reported that the value of this famous reservoir was not in excess of its cost.

According to my Exhibit 30 and my testimony in this case, I have found that in the period from 1900 to 1914, inclusive, in only three years, to-wit, 1900, 1909 and 1914 could the reservoir have been filled to its capacity of 79,064 acre feet. You could increase your average storage by increasing the height of the dam, thereby getting a little more water three years out of fifteen. Whether that would justify an increase in capacity from 80,000 acre feet to 100,000 acre feet is a matter of balancing the cost with what water you get.

But my advice to Mr. Bates to build a reservoir with a capacity of 100,000 acre feet was based upon my report that he would be able to get 20,000 acre feet from the south fork. It was not a matter of enlarging Lake Cheesman, but of making an original investment in a new reservoir.

On my assumed draft of 40,000 acre feet per annum, as shown by Exhibit 32, the reservoir is full at times and water escapes over the spillway, but that, of course, is because of the smallness of the assumed draft. With a larger draft that would not have occurred.

649 In the Bates report (Exhibit A-66) on April 24, 1908, I stated that the limit to which I advised him to build his reservoir was 100,000 acre feet capacity, and that "The reason for this is that the canal priorities below require from 300 to 600 cubic feet per second; that this water will be taken from the north fork first, allowing Lake Cheesman to store the water of the south fork." Just prior to that time I had reported to the board of appraisers, as shown by my written report, that the required flows were: April 332 cubic feet per second, May 854, June 875, July 935, August 329, September 267. I do not consider those two statements irreconcilable. In the present case I state that the required flows in the same months are *are* as follows: May 500, June 1000, July 1000, August 700, September 400. There is quite a difference between my report to the board of appraisers and my statements to Mr. Bates in this regard. "I will have to look that up and see just how—I have to refresh my memory on that. I can't say now just why it was."

In this case, and also in my report to the old board of appraisers, the basis of my determination was that Cheesman could store all of the flow of the south fork whenever there was sufficient water in the main river to supply the priorities below; that is, that the north fork must be exhausted to supply those priorities before there is any demand on the south fork. According to my testimony and my exhibits in this case, after those priorities below have been satisfied there are very few occasions when there is any excess left in the north fork. That also was what I found and reported to the board of appaisers, to-wit, that after satisfying those priorities from the north fork there was only about 16,000 acre feet left. Nevertheless, sixty days later I stated in the Bates report: "I am of the opinion that a reservoir of 80,000 acre feet is justified on account of the north fork supply alone." I had not found any more supply in the north fork between the date of my report to the old board of appraisers and my report to Mr. Bates. The Bates report refers to the capacity of reservoirs, not to the average available supply, but I would not say that an 80,000 acre foot capacity in a reservoir is required to store an average supply of 16,000 acre feet.

Exhibit A-67 is a transcript of the tables submitted in my report to the old board of appraisers, and which formed the basis of my conclusions in respect to available storage in and the efficiency of Lake Cheesman.

Exhibit A-67 explained. Column 3 indicates the quantities furnished by the north fork and the south fork, respectively, to supply the canal demands. Column 5 shows the total amount
650 available for storage, not limited by the size of the reservoir, or its condition, as to whether it is at the time full or not. Column 6 states the amount withdrawn from the reservoir, under an assumption of an annual draft of 45,000 acre feet. Column 9, the deficiency, if any, under the 45,000 acre foot assumption. I do not know where I obtained the quantities set down as to flows, in column 1, for the years 1900 and 1901. I have stated in the

testimony here that there were no official records of those flows for those years.

Exhibit A-67 presents, in one set of tables, the information contained in my Exhibits 30 and 32 presented in this case. Upon a consideration of these tables, I advised the board of appraisers that the operation of the lake at an annual draft of 40,000 acre feet was the best that could be done, and applied a unit price of $40 per acre foot to that quantity, making a total of $1,600,000 for the Lake Cheesman property.

The board of appraisers had this matter under advisement until March, 1909, but I never advised that board of any change in my conclusions as the same were presented in said written report to them.

I advised the board of appraisers, and it was my opinion, that after satisfying priorities in Districts 2 and 8, 16,000 acre feet on the average was all that could be obtained for storage from the north fork, and that after 40,000 acre feet per year has been furnished from Lake Cheesman little, if any, water is available for storage from the south fork. Notwithstanding that, I advised Mr. Bates to build a reservoir, having a capacity of 100,000 acre feet, to catch the storage waters available in the north fork and south fork, subsequent in point of time, and therefore taking water only after Lake Cheesman's priority was satisfied, and to expend therefor the sum of $1,295,000. I concluded, and advised Mr. Bates, that a reservoir with a capacity of 100,000 acre feet, built at the location proposed, and at the cost mentioned above, and dependent for its supply of storage waters solely upon the waters of the north fork and the south fork of the South Platte, would store and deliver annually 50,000 acre feet. That was the statement in my report to Mr. Bates. The report was written to determine the relative merits of these three reservoirs mentioned herein. I made the assumption of an annual storage of 50% of the capacity. I found that Cheesman, on a similar stream, could deliver about fifty per cent, and possibly I had that in mind, and on that assumption of 50,000 acre feet I stated in the Bates report: "The revenue derivable from the conservation of 50,000 acre feet of water is at least $2,000,-
000, showing the Highline and the Eagle Rock feasible finan-
651 cially, with a probable profit in the former of $715,000 and
in the latter of $158,000, while the Two Forks would involve an actual loss of $220,000."

My judgment in April, 1908, was, as expressed in the Bates report, that, in addition to satisfying the priorities of Lake Cheesman, 10,000 acre feet per annum on the average would be furnished from the south fork, but that 20,000 acre feet could be gotten quite often. By the time the Bates report was made I had considerable more data and had studied the subject quite a bit more than when I made my reports to the old board of appraisers. But I had arrived at no different opinion, and had found no additional water available for storage in the south fork of the South Platte which I did not know of when I made my report to the old board of appraisers.

In making the Bates report I think I also took into consideration the use of Lake Cheesman for domestic purposes, and not for irrigation purposes. I think I advised Mr. Bates to make the investment of over a million and a quarter dollars for the construction of his reservoir in the hope that the Water Company would continue the use of reservoir for domestic and city supply purposes, and that in that use it would often be left full, or relatively full, so that water might flow over the spillway, and in spite of the fact that under Lake Cheesman's decree it may completely empty and completely fill its reservoir each and every year to its full capacity.

The results which I obtained and testified to in this case as to the available storage for Lake Cheesman are the same exactly in quantity as the results which I ascertained and reported to the former board of appraisers, to-wit, 40,000 acre feet per annum.

Since the date of the Bates report other rights have intervened, such as the Antero and Lost Park reservoirs, the Henrylyn and Standley Lake projects, etc. Conditions have now so changed that a recommendation at this time to build a storage reservoir of 100,000 acre feet to store the waters of the South Platte would not be justified.

According to the facts set forth in Exhibit A-67 and reported to the old board of appraisers, even if Lake Cheesman had had a capacity of 100,000 acre feet, instead of 80,000 acre feet, it could have made an increased storage only in the year 1900, which distributed over the five year period, 1900 to 1904, shown in Exhibit A-67, would have increased the average by 4,000 acre feet only. According to the facts set forth in my Exhibit 30, if Cheesman had had a capacity of 100,000, instead of 80,000 acre feet, it could have got an additional 20,000 acre feet in 1900, and after that, for the period 1900 to 1913 inclusive, some additional quantity, on account of additional capacity, only in the year 1909, making an addition
652 to the average available storage for that period, limited by the capacity of the reservoir, of only about 2,000 acre feet annually. But upon an assumed annual draft of 40,000 acre feet, as shown by Exhibit 32, the result would have been different.

The amount left in the reservoir at the end of each year depends upon the draft placed upon the reservoir. As the draft is increased the amount carried over in the reservoir is decreased. Disregarding the assumed annual draft, it is true that in the whole period 1900 to 1913, inclusive, according to my estimates here made and as presented to the old board of appraisers, the total quantity of water available for storage in Lake Cheesman exceeded the capacity of the reservoir only in the years 1900 and 1909.

(Exhibit A-66, the Bates report, admitted over objection and exception.)

(Exhibit A-67, transcript of tables presented to old board of appraisers, admitted.)

(Exhibit A-65, transcript of Mr. Field's testimony in Wyoming vs. Colorado, admitted over objection and exception.)

Suggested corrections in Exhibits 30 and 32 reviewed. Will not admit correction for 1911.

Letters of Cogswell, Division Engineer, referred to to show that the actual storages were improperly made.

I do not think the records showing the amount of water at Lake Cheesman, the inflow and the amount stored during June and July, are correct. If they were incorrect, then Mr. Comstock's corrected stream flow, based thereon, would be incorrect. Therefore, because of uncertainty, I have allowed no storage in June and July, 1911. My construction of division engineer's orders is that there was a practical prohibition against storage in Lake Cheesman from June 1st until the end of the year 1911. If you deduct all the water actually ordered by the division engineer to be turned out, there would still remain approximately 14,000 acre feet of actual storage made in 1911 and permitted to be made; but my further theory is that there existed from June 1st to the end of the season a continuous prohibition against storage, and therefore there should be deducted any additional quantities stored during that period.

Further explanation of changes to be made in Exhibits 30 and 32. Will present amended exhibits.

The assumed annual draft of 40,000 acre feet may not be the draft upon which it should be operated for irrigation purposes. It might be that a draft of 50,000 acre feet would be advisable; but if you assume a draft of 40,000 acre feet, you get a better price per unit. If you assume a draft of 50,000 acre feet you get a less price per unit, but the gross result is about the same. On a 50,000 acre foot draft the unit price applicable would be $40 per acre
653 foot. The difference in efficiency between a 40,000 and a 50,000 acre foot draft, under my estimates, would make a difference in price per acre foot of $10. The amount of shortage below the assumed supply, in each of the years when a shortage occurs, must be considered. Assuming that shortages occur in three years out of a period of 13 or 14, such shortages must amount to as much as 50% in each of the three years to justify a reduction in the unit price from $50 per acre foot to $40 per acre foot. I mean by that the average shortage for the three years. In the period here estimated is included the year 1902, a year of exceedingly short supply, producing a shortage very much greater than in the other two years where shortages occurred.

I experimented somewhat with a 50,000 acre foot draft, and found shortages after the year 1904 in the years 1910 and 1911, but I don't remember just how the deficiencies came out. This is a matter more of experience than judgment. I do not know that I can reduce it to a mathematical calculation. I want to say right now that on a 50,000 acre foot draft $40 per acre foot is my opinion of what the value of the water is, and on a 40,000 acre foot draft the value of the water is $50 per acre foot. I have not actually made a table upon an assumed draft of 50,000 acre feet, and do not know just what the shortages or the percentages of shortage would be. When I amend my exhibits I will present such a table.

I know of no large reservoir in this neighborhood that has no shortages in the like period of fourteen years. They have all had them. I think it would be uneconomical to operate a reservoir and

not have an occasional partial shortage. I do not know of any reservoir on this side of the range in Colorado which has not had a shortage in its contracted supply in the last fourteen years.

My exhibit 32, on an assumed draft of 40,000 acre feet, shows a deficiency in one year only, to-wit, 1904, in the period 1902 to 1913 inclusive. If I had included the years 1899, 1900, 1901 and 1914, there still would have been a shortage only in the one year, 1904. If the assumed annual draft had been 50,000 acre feet during that same period of fifteen years, shortages would have occurred in my opinion, in three years.

In my report to the old board of appraisers I stated with respect to the years prior to 1900 that there were no records pertaining thereto which were sufficient to be of service.

I now assign a price of $50 per acre foot for a supplemental supply. In 1907 I assigned a unit price of $40 per acre foot for a supplemental supply.

The value of group 1, Platte Canon rights, Bear Creek rights and Lake Marston. I now assign to the summer flow of the
654 Platte Canon ditch a unit price of $4,000 per second foot.

In my report to the old board of appraisers I assigned a unit value thereto of $2,000 per second foot. Since 1907 there has been an increase in the value of direct flow rights, but not to that extent. Under normal conditions, both land and water would be more valuable now than in 1907. The demand for water is greater than in 1907, and, the quantity being limited, the greater the demand the higher the price.

As to the winter flow of Platte Canon ditch, I reduced that from 56 to 50 cubic feet per second and assumed that it might be stored in Lake Marston. I made that reduction because, as stated in my direct examination, certain persons have a right, as against the Water Company, to receive water for irrigation from the Platte Canon ditch. If it should be wrong in making that deduction from the winter flow, as well as in the summer, the additional 6 second feet flow during the winter season would afford 1800 acre feet. 56 second feet flowing during the non-irrigation season would produce approximately 16,912 acre feet. Of this I assume that 14,000 acre feet would be stored in Lake Marston. I made a rough assumption that the river would not furnish the full quantity of 16,912, and therefore took 14,000 acre feet. I did not go into details as to that. To that 14,000 acre feet, and to the water coming into Marston Lake from the Bear Creek source, I assigned a value of $40 per acre foot. I assigned a different value to the product of the Platte Canon ditch during the irrigation season because there was no stored water. You must use direct flow water when it is flowing. If Lake Marston could be so operated in connection with the Platte Canon ditch that the product thereof in the irrigation season is deliverable like storage waters, you could get a higher price for that. But I do not see why merely running water through a reservoir should increase its price.

Except for Lake Cheesman, the Bear Creek rights and a portion of the winter flow of the Platte Canon ditch, which I deemed storable in Lake Marston, all of which I valued on an acre foot basis, the

remaining water rights of the company were valued by me on a second foot basis. Second foot is an expression of the rate of flow, rather than of quantity. Value of second foot rights in different ditches — likely to differ greatly, although ditches be close together and taking their water from the same stream; for example, the Highline ditch and the Platte Canon ditch. A second foot right depends for its value on the quantity of water which it will furnish, and also upon the time of the year when the water is furnished. A certain quantity of water under a second foot right furnished during the months of July, August and September would be worth more than the same quantity of water furnished under a second
655 foot right during the months of May and June, although both rights were reliable. In the case of the Platte Canon ditch, which furnishes a constant flow throughout the irrigation season, the water furnished under that constant flow during the later months of the irrigation season is worth more than the water furnished thereby at other parts of the year. Even under such a constant flow, the water furnished by the direct flow right in the latter part of the irrigation season, when the need is greatest, is worth less than the water furnished during those same months of the irrigation season which has been stored in a reservoir and held until that time, because with stored water you are able to conserve it, even for a day, or two or three days, and then turn it on in almost any volume that your necessities, convenience, economy of use and operation dictate. You can shut it off on Sundays and holidays, and when there are copious and continued rains, thus adjusting your use of the reservoir water to reach the greatest economy. This you cannot do with a direct flow right, even one as old and reliable and constant in flow as the Platte Canon ditch. Even though you had an equalizing basin to equalize the direct flow, it would not be worth as much as stored water, because the stored water could be used at any time of year. The beauty of reservoir water is that, you have it absolutely under your control, you can vary it in volume and you can vary it in time. You can often carry the reservoir water over into the next year, while with a small regulating reservoir you cannot. You can actually go out and purchase these direct flow rights for less than you can the reservoir rights, and it is the market value, of course, on which I would base by judgment. Those are the direct flow rights usable directly out of the ditch, and dependent upon the vagaries of the stream and the flow of the ditch as to when the water can be used.

In valuing group No. 1 I included the Platte Canon filter galleries, item No. 8, to which I subsequently gave a separate value of $38,252. This should be deducted from group No. 1, leaving a value for that group of something less than one million dollars. Deducting the structure values, a considerable deficiency appeared.

As to items 5 and 6, the Mississippi Street galleries, I applied my unit price per second foot to the actual diversions that had been made by the galleries, to-wit, $1500 per second foot for the summer flow, $1100 per second foot for the winter flow, considered as five-sevenths of the summer flow, making a total of $26,000.

I cannot imagine a situation when the city of Denver would be actually without any water supply at all, and if it were obtaining a water supply from sources other than The Denver Union Water Company, there would be the same return flow into the
656 stream from the sewage. But if the city took its water supply from new sources, it might be able to dispose of the sewage as it pleased, because there would be no accrued rights to the return from that particular water. That might be true if the city brought the water across the range, or obtained it in South Park. If the city bought rights on the South Platte river now devoted to irrigation purposes and changed them to a domestic use, of course the demands for irrigation purposes would to that extent be diminished.

The total value on items 5 and 6, Mississippi Street galleries, found by me was $26,000. Values have increased since 1907. Nevertheless, to these same rights I assigned a value of $33,000 in my report to the old board of appraisers. I have applied my unit prices to the actual quantities diverted, and not to the capacity to divert.

Item No. 7, Cherry Creek galleries. My present value, $10,000 gross, same value assigned in report to board of appraisers in 1908.

Item No. 8, Platte Canon galleries. Present valuation $38,252; in report to board of appraisers in 1908 $1,238. In making my estimate of storage in Lake Cheesman I had assumed that this right would flow constantly at the rate of 10 second feet, therefore in valuing this right, to be consistent, I have to make the same assumption, and so valued it at $4,000 per second foot.

Items 9 and 10, the two Platte Canon conduits. Adopted Mr. Anderson's valuation. In 1908, in report to the board of appraisers, I valued item 9 at $2,475. I now value it at $24,750. This time I took a quantity of 24.75 cubic feet per second and applied to it a unit price of $1,000; on the former occasion I took the same quantity and applied a unit price of $100 per second foot. I have changed my mind about it since 1908. As to item 10, the other conduit right, I valued it at this time at $30,464; in 1908 I valued it at $100 per second foot for 38.08 second feet, making $3,808. The same explanation as before.

As to item 20, Lake Archer power right, and 21, Rough and Ready power right, I have not upon this occasion placed any value upon them. I have left them out because of an assumption I made that they should not be included in a value for rate making purposes. Item 22, power right of the Platte-Denver ditch, I omitted for the same reason. In 1908, in my first report, I assigned to the Lake Archer power right, item No. 20, a value of over $190,000, which I reduced in my supplemental report to $32,600. This time I have left it out entirely. As to item 21, Rough and Ready power right, in 1908 I valued that at a total of $63,270; this time I have omitted it entirely.

657 From the total value of Lake Cheesman as found by me I deducted structure values as found by Metcalf and Anderson. Deducting these left a net value, on the basis of $50 per acre foot, of $573,223, or on the basis of $40 per acre foot, of $173,223.

It may be that the structures are valued too high, or that the character of the structures is not justified when the water is used for irrigation purposes. In my report to the board of appraisers I stated, after determining a total value for Lake Cheesman of $1,600,000, "It may seem surprising that this famous reservoir's value for irrigation purposes is not in excess of its cost." It may also seem strange at this time that for irrigation purposes this "famous" reservoir is not worth more than the sums mentioned above in excess of its cost.

As to all of the other water rights of the Water Company, considered as entities, I have in each instance determined that the value of the entity for irrigation purposes was less than the reproduction cost of the structures appurtenant thereto. This character of structure for irrigation purposes is not the correct character of structure, nor what would be built for such purposes. I found some deficits to exist in respect to each water producing property except Lake Cheesman, the two Platte Canon conduits and the Highline ditch rights. But in respect to the other water rights I found a sufficient deficit so that deducting these deficits a net water right value on the entire plant was found of $429,189. If such a deficit is found as to a particular right, I do not think the Water Company owes that money to anyone. If a man has one water right which is worth less than nothing for irrigation purposes, that does not mean that other good water rights which he has are worthless by reason of that fact. I simply presented those figures for the information of the court. He will exercise his judgment as to whether this deficit is to be deducted or not. In valuing this plant as a whole I think really it would have to be deducted as I have done in that respect. In 1908 I found such a deficit to exist, even in respect to Lake Cheesman.

My estimates here have been of a valuation of these water rights for irrigation purposes. For irrigation purposes different and less expensive structures would have been provided. The structures as they exist were fully justified considering the use to which the water was to be applied, namely, domestic, municipal or city supply uses. When you sell your water for domestic purposes you get interest on the value of your water rights, pure and simple, as such; you also get interest on your structures as such, and the combined revenue justifies the acquisition of the water and also the construction
658 of the plant. Whether in that view of the case any deduction should be made from water right values because of structures is a question I am not prepared to discuss The owners and projectors of these water works are entitled to have a greater value because of these expensive structures than if the water rights were devoted to irrigation purposes. But I do not think the water itself has a higher value because used for domestic purposes. In my report to the board of appraisers in 1908 I said: "It may be argued that water for domestic and municipal purpose has a higher value than obtains for agricultural use, and this is true." Nevertheless, the value of the water right is based upon its value for agricultural purposes. A city can afford to pay more for its water than a farmer can, and therefore it is true that for municipal purposes it has a

higher value. The water right itself might be purchased at its value for irrigation purposes, but it costs more after you have it to develop it for city use than it does to develop it for irrigation purposes, because of the difference in the cost of the structures. The owner of an adequate water right which he is devoting, together with the structures which have developed it, to the supply of a city, is entitled to get a return, first, upon the agricultural value of the water right, second, upon the value of the structures which he has been required to install for the purpose of making it available for city use, or upon the aggregate of the two. The value of the water right for irrigation purposes might be taken and an average or normal amount deducted for the value of the average or normal irrigation structures. The average or normal irrigation structures would, except possibly in the case of Lake Cheesman, cost considerably less than the expensive water works structures here existing.

Redirect examination:

Exhibit 30 was present for the purpose of estimating what might be expected in the future. My estimate presented to the old board of appraisers was on a purchase basis. In the Bates report I considered the future of Lake Cheesman on the basis of domestic use. (Objected to as being in conflict with the language of the Bates report. Overruled, Exception.)

There was a conflict in the United States' land office relating to the rights of way for these three reservoirs, and the Bates report was written to determine the relative merits of the three sites for irrigation purposes.

My Exhibit 30 was prepared without any reference whatever to the criticisms I had made of the testimony of Mr. Comstock
659 and Mr. Anderson and their exhibits. That criticism was an entirely different and distinct matter.

In the case of Mr. Anderson, the percentage of error, based upon gross figures of allowance and gross figures of error, was 29.4%.

As to Exhibit 35, the deductions made on the last page to reach the final amount, measured in acre feet, aggregated ten per cent. Applying a ten per cent reduction to the figures above relating to Districts 8 and 2 respectively, there remains as the final amount for District 8 104,700 acre feet, and for District 2 115,767 acre feet.

The average storage as shown originally by Exhibit 30 was 48,380 acre feet. Making the corrections admitted, except for the year 1911, would add 400 acre feet to the average. If the correction suggested for 1911 were made it would add another 400 acre feet, making a total of 800 acre feet.

The accretions to the steam in Districts 8 and 2 are not available to ditches in the upper ends of the districts. The Highline must get practically all of its water from the canon, except accretions where it crosses Plum Creek; and the Burlington, at the head of District 2, receives the accretions from the Denver sewage.

If ditches on streams tributary to District 2 were shut down and the water allowed to flow into the main stream, the Burlington would be benefited, even though the water entered District No. 2

below its intake, because the needs of other ditches below would be supplied and demand on the stream flow at the Burlington intake decreased. But this would be quite remote.

The private marks, mentioned in cross examination, by which water commissioners estimate the flow in ditches, are pegs driven in the bank of the ditch, or points on the pier of a bridge, etc. He places these where they can be seen from the road as he drives along. The water commissioners and their deputies go by these private marks to quite an extent.

When Mr. Anderson and Mr. Comstock assumed that a portion of the yield of the Platte Canon ditch could be stored in Lake Cheesman it was an assumption of a right to convert a direct flow right into a storage right. It really involves a change of the point of diversion.

The year 1912 did not produce a full reservoir at Lake Cheesman, according to my Exhibit 30, which represents my best judgment in the matter.

The object of my testimony in the Wyoming-Colorado case was to show that if water were diverted from the Laramie into the Poudre a great benefit would accrue to the district, to the state, and to the public generally. I endeavored to show what that
660 water would accomplish in the Poudre valley, including its use and re-use.

According to the 16th Biennial Report of the State Engineer, covering the years 1911 and 1912, average duties of water for the year 1912 are shown as follows: District No. 3, 1.98 acre feet per acre; District 4, 1.85 acre feet per acre; District 5, 1.76 acre feet per acre; District 6, I did not average; District 7, 1.6 acre feet per acre; District 9, 3 acre feet per acre. I think District 9 is most nearly comparable with District No. 8 in respect to the character of the soil and character of crops raised, although a large part of District 9 is adobe. I think District 1 more nearly compares with District 2 than any other, and also with District No. 8. I do not know what the average diversion in District No. 1 has been, but individual diversions for the year 1912 were as follows: (List of individual diversions given.)

Applying a method similar to that used by me in the Wyoming-Colorado case, I found a consumptive use of water in District No. 8 of about ¾ of an acre foot per acre, showing that the return to the river from the use of these waters is very large. The physical conditions for the re-use of water in District No. 8, on the Platte, are not so good as on the Poudre. The water coming back into District No. 8 is re-used in District No. 2

The duty of water is ordinarily determined at the headgate of the ditch, or if reservoir water, at the reservoir. This duty differs from the amount of water applied to the land, because of the losses in transit. The amount diverted by ditches is measured at the headgate. The demand of the several ditches is considered at the headgate.

I did not examine the tables prepared by me for the old board of

appraisers in preparing for my testimony in this case, but the ultimate result is practically the same.

(Exhibit A-67 compared with Exhibits 30 and 32.)

As to the apparent conflict between my report to the board of appraisers in relation to the supply and my report to Mr. Bates, I believe that I have explained that about as fully as I can. There is nothing further that I want to say upon that subject. In making up the Bates report, I was considering only the comparison between the reservoir mentioned.

In considering the value of the Platte Canon ditch right, I also considered that the Rough and Ready power right was of benefit, in that, being in the same ownership, it would not interfere with the Platte Canon ditch right, and therefore made the Platte Canon ditch right a better right.

In this case I have considered the water rights of The Denver Union Water Company upon the same basis as when I made
661 my report to the former board of appraisers. Of course in this case, being for rate-making purposes, I left out certain rights which appeared not to be involved in a rate-making case.

The rainfall along the foothills to the west of Denver in Districts 3, 4, 5, 6, 7 and 9 is greater than it is east of the Platte river and in the immediate vicinity of Denver. There is somewhat less rainfall in Districts 2 and 8 than in the other districts mentioned.

Recross-examination:

Mr. Fellows cooperated with me in the preparation of the reports filed with the old board of appraisers. The Bates report, Exhibit A-66, was my own individual production. Mr. Fellows did not cooperate with me in that, but I think he had knowledge of it at the time. I might even have consulted him; I do not remember. There has been a copy of it on file in the office since that time.

There was no difference in the principles of valuation applied by me in my report to the board of appraisers and in my present testimony. In the present instance I left out some of the property that I thought was not used or useful, or reasonably necessary to use for the city's supply.

I think the Bates report, Exhibit A-66, was based upon a theory, which I then had in mind, that Lake Cheesman was then and would always thereafter continue to be a reservoir for domestic and city supply uses. I think I must have had that in mind. It is a long time ago to have any definite recollection on the subject. Whether I had that idea in mind then or not, it would not make a very great difference in the conclusions which I might draw in my report to Mr. Bates. I cannot say positively that in preparing the Bates report, and in estimating possible storages for the Highline, Eagle Rock and Two Forks reservoirs, I assumed that Lake Cheesman would continue to be used for domestic and city supply purposes. I have not the notes, or anything of that kind, and cannot say positively.

In the Bates report I recommended the same additional reservoir capacity for the south fork, whether it should be by way of addi-

tion to Lake Cheesman itself or in the new reservoir to be built by Mr. Bates and used for irrigation purposes. In the Bates report, in ascertaining how much was left in the way of reservoir capacity justified for irrigation purposes, I estimated a total justified reservoir capacity for both the north and south forks of 180,000 acre feet, from which I deducted the total capacity of Lake Cheesman; nevertheless, I do not think that I was necessarily dealing with
662 Lake Cheesman upon the same basis as I was dealing with the reservoir which Bates proposed to consrtuct. We were dealing in averages. I am, nevertheless, of the opinion that I based that report upon a consideration of Lake Cheesman solely as a reservoir for domestic supply.

In respect to the efficiency of Lake Cheesman and the quantities which it may store, I have in this case arrived at practically the same figure determined and reported by me to the old board of appraisers.

On re-direct examination I stated that Anderson's percentage of error was 29.5. That was a mistake; it was 24%. That percentage was determined by consideration of the years 1909 to 1913, as shown by Mr. Anderson's Exhibit A-32, by deducting therefrom when according to my assumption deductions should be made, but adding nothing thereto when according to my assumptions Mr. Anderson's estimates were too low.

The percentage in respect to Comstock was determined with respect to the same years and in the same manner as that relating to Anderson.

No such percentages would have been obtained if I had compared the figures of Anderson and Comstock with those contained in my own Exhibit 30.

As to my Exhibit 35, last page: the deductions made by me amounted in the aggregate to ten per cent, but month by month they were as follows: April 10%, May 2%, June 15%, July 14%, August 5%, September 8%, October 10%.

There are large accretions to the river in District No. 8, and their effect begins to be felt above the head of the City ditch, which is the ditch of the Platte Water Company. All the ditches in District 8, except the Highline and the Last Chance, are below that point and would receive the benefit of the return flow in District 8. The seepage and return flow in District No. 8 is also available to the ditches in District No. 2, even those at the very head of that District, including the Burlington. Moreover, the Burlington has the benefit of the inflow from Cherry Creek, and the inflow from the Denver sewers, which is always large and quite constant. In preparing my Exhibits 35 and 30 I deducted all of the seepage and inflow in District 8, as estimated by me, from the demands of District 2 upon the flow at Denver.

The shutting off of the ditches in districts tributary to District 2 would increase the supply of the Burlington, even though the tributary streams entered the main stream below the Burlington intake, by decreasing the demand of the lower ditches in District 2
663 upon the stream flow at the headgate of the Burlington.

The private marks of the water commissioners further described.

When a ditch is drawing reservoir water, it is the duty of the water commissioner to report that fact, and in my Exhibits 33, 34 and 35 I have intended to show such fact whenever it appears in the water commissioners' reports. Sometimes reservoir water is transferred through the river from one reservoir to another.

On my re-direct examination I omitted to give the average duty of water for the year 1912 in District No. 6. It now appears that that average duty was 1.03 acre feet per acre per annum. That is a higher duty and a greater accomplishmerft by the same quantity of water than in any of the districts which I did mention on re-direct examination.

There may be some duplication of acreage in determining these water duties. I do not know to what extent. I would not say to a large extent.

As to District 9, the Arnett ditch and the 2800 acres under it, which I omitted: That ditch is otherwise known as the Harriman ditch, and its diversions consist not only of diversions to irrigate said 2800 acres, but also to supply the city and county of Denver. That is the ditch which furnishes Marston Lake, and therefore, of course, should not be included in determining the duty of water for irrigation purposes. I did not mention this fact on my re-direct examination.

In Exhibit A-67, the tables presented by me to the old board of appraisers, I calculated and deducted evaporation for each month. In Exhibit 32 I deducted the constant quantity of 3000 acre feet each and every year, as an average amount. The more correct and logical method is to determine and deduct each month. I do not know what result I would have arrived at if I had used that method in respect to Exhibit A-32. I will review the evaporation in that way when I present my amended exhibits.

Aside from evaporation, I do not think the losses from Lake Cheesman are a matter of any considerable consequence. Exhibit A-67 presents all of the tables which I presented to the old board of appraisers upon this subject.

Records of precipitation in Districts 3, 4, 5, 6 and 7, as compared with Districts 8 and 2, discussed.

Redirect examination:

Exhibit 36 *are* copies of letters of the division engineer relating to storage in the summer of 1911, and referred to in my cross examination. (Exhibit 36 admitted.)

664 Recross-examination:

Exhibit 36 contains all of the letters written between June 19th and December 3rd, both dates inclusive, relative to the storage of water in Lake Cheesman or in Antero.

Redirect examination:

Exhibit 45 is a corrected exhibit, embodying certain corrections in my original estimate of Lake Cheesman upon the assumption of a 40,000 acre foot draft, and also an estimate on the assumption of a

50,000 acre foot draft. The last sheet of Exhibit 45 also shows the precipitation at the different stations. The evaporation has been deducted each month; the evaporation determined for each month being shown on page 1. (Exhibit 45 admitted.)

Exhibit 46, consisting of five sheets, marked pages 2, 4, 5, 6 and 7, are sheets bearing corrections necessary on account of errors appearing upon sheets with corresponding numbers in Exhibit 45. They are to be substituted for the original sheets. (Exhibit 46 admitted.)

Recross-examination:

The corrections made by Exhibit 46 relate to errors in Exhibit 45, in the calculation of evaporation. For instance, in January, February, March and April of 1902, no evaporation should have been deducted, because in those months the reservoir was full, and there were additional quantities in the river available for storage under the appropriation. So long as the reservoir has not exhausted its right to store in any particular year, by having taken from the river in total quantity 79,064 acre feet, according to the method I have here employed, it is entitled to take available storage water to fill up a vacancy in the reservoir, even though it be caused by evaporation. I have so treated that matter throughout these tables in Exhibit 45, as corrected by Exhibit 46. The other sheets in Exhibit 46 make similar corrections.

In computing evaporation, I applied my factor of evaporation to the stage of the reservoir as it existed on the first day of the month that I was considering, and not to the average area for that month. The rate of evaporation varies with the different months. I might have got more accurate results if I had taken the average exposed area for each month.

According to Exhibit 46, there was a full reservoir in certain months in 1908, notably March and April; also in September, 1909, and in January, February, March and April, 1910. Nevertheless, quantities of evaporation are set down opposite these months. These
665 quantities ought to be deducted from the total of evaporation, appearing at the foot of the column.

Exhibit 46, sheet 6—January, February, March and April 1910; there being a full reservoir and available storage, the quantities of evaporation should be eliminated from the evaporation column, and the aggregate of those figures deducted from the total at the foot of that column.

Exhibit 45, as amended by Exhibit 46, in its first part, covers my assumed draft of 40,000 acre feet and the operation of the reservoir under that assumption, following which is a table upon an assumed draft of 50,000 acre feet. As to the 40,000 acre foot draft, it is identical with Exhibit 32, except that evaporation has been dealt with month by month.

The evaporation factors applied in Exhibit 45 and shown on table 1 were obtained as follows: From Wilson's Irrigation Engineering I took the data for the evaporation at Denver and at Colorado Springs, and took something of an average between the two. I think the evaporation at Cheesman would be somewhat less than the aver-

age of those two, but considering the matter of wastage and seepage from the reservoir, I thought the average was fair. The quantity which I took as the vertical loss in each month, as shown on page 1 of Exhibit 45, was not the average of the quantities given by Wilson for Denver and Colorado Springs. I have made no experiments to ascertain what is the actual loss by evaporation at Lake Cheesman. The figures on page 1 of Exhibit 45 as to the respective months are sometimes more and sometimes less than the average of the figures for Denver and Colorado Springs as given by Wilson.

I examined the evaporation at Cheyenne and other places and that influenced my judgment somewhat. Evaporation at Cheyenne is a great deal more rapid than at Cheesman, because of the wind, and because it is on the plains. I also examined the evaporation at some other places, like Santa Fe. The evaporation from Lake Cheesman is less than from a shallower body of water. The depth of the lake tends to keep the water cool. The rate of evaporation at Lake Cheesman would be less than at Fort Collins.

There is an agricultural experiment station, at the agricultural college, at Fort Collins. I have seen their Bulletin 45 on the subject of evaporation. I did not know that the average annual loss from evaporation on a tank placed near Fort Collins, at an elevation of 4990 feet, was shown to be 3.4 feet. The average annual evaporation computed by me for Lake Cheesman, as appears in Exhibit 45, page 1, is 5.25 feet. But that covers all other losses. I cannot say what the other losses amount to. I did not consider precipitation at Lake Cheesman in determining loss by evaporation. The
666 precipitation probably belongs to the river, therefore I have made no deduction from evaporation on account of precipitation.

Said Bulletin 45, issued by the agricultural experiment station, states, as to said evaporation loss of 3.4 feet: "The amount given as the evaporation is the loss from the water surface after allowing for the rainfall, or is the fall of the surface plus the rainfall." If said Bulletin 45 states that the annual loss of 3.4 feet is the gross loss by evaporation, without deducting anything from it at all on account of precip-tation, I think the experiments must have been wrong. My theory is that the water which comes from the clouds and falls on the surface of the lake is water which if the lake were not there would belong to the appropriators below—that is, whatever reached the river, or in the order of its priority would belong to the lake itself; but to say that Lake Cheesman had, whenever there is a rainfall, to let out of the lake whatever has fallen on it is cutting it entirely too fine. If the lake were not there, not all of the water which now falls on the surface by way of precipitation would reach the river. A third of it might. Therefore, I am willing to admit that two-thirds of the precipitation ought to be deducted from the gross evaporation.

The gross evaporation loss at Lake Cheesman is approximately 5 feet vertically; the gross loss on account of other losses is at least a foot and a quarter, making a gross vertical loss of six and a quarter feet. From that 15 inches may be deducted for precipitation. For the purpose of getting past this question, I have assumed that the

evaporation there is approximately five feet; that the precipitation is about a foot and a quarter; that the losses from sources other than evaporation are approximately equal to the precipitation. That is what I have done. I made those assumptions without and investigation. I do not know what the losses from the reservoir are, and I do not know that the precipitation exactly, or even approximately, equals such losses. The losses from the Two Buttes reservoir, on the plains in Southeastern Colorado, are approximately that. That reservoir is retained by an earthen dam about 80 feet high, and has a capacity of about 50,000 acre feet. This is the first year that it has been filled. In the course of three weeks the loss from the surface of the Two Buttes reservoir was nearly two feet. It is well known that a reservoir on the plains, retained by an earthen dam, and particularly in the earlier years of its life, is subject to very much greater losses from seepage and other like causes than a reservoir like Lake Cheesman. There are no evidences of any leaking through the granite bed of Lake Cheesman that I know of.

I do not want to be committed to saying that one and a quarter feet is an accurate statement of the annual losses from Lake
667 Cheesman on account of causes other than evaporation. I really intended to give credit to Lake Cheesman for the amount of precipitation, but regarded it as being offset by the losses from the lake otherwise than by evaporation. All of the precipitation falling on the lake surface should not be credited to the lake. I took this into consideration. I think I deducted enough on account of precipitation to balance the losses from other causes than evaporation, which losses, for purposes of illustration, I assumed were one and a quarter feet vertical per annum. If there be any loss by seepage from Cheesman, I would say that it does not reappear in the stream before the intake of the Highline ditch is reached. If there is any wastage other than seepage, it immediately reappears in the stream, being discharged into the stream immediately below the dam.

Exhibits 45 and 46 further explained. Exhibit 45, last page relates to precipitation. It pertains to the inquiry which arose in respect to the relative average rainfall in Districts 8 and 2, as compared with Districts 3, 4, 5, 6, 7 and 9. The table shows that the average precipitation on a meridian running through Cheyenne, Greeley and Denver is less than the average precitation on a meridian to the West running through Boulder, Longmont, Loveland and Fort Collins, just at the westerly edge of the districts. Instead of taking the precipitation at Loveland I took it at Boothroyd's ranch at Waterville. That ranch is to the West of Loveland, in the foothills, and inside of the Big Thompson canon. There are official records of the precipitation at Loveland proper. They are official records, and show a considerably less precipitation than appears from the records at the ranch in the foothills to the West.

I think the average of the rainfall at Greeley and Fort Collins ought to fairly represent the average of District 3. That average is less than the average rainfall at Denver. The average of Denver and Greeley would fairly represent District No. 2. That average is

slightly less than the average of Greeley and Fort Collins, the one being 13.75 inches, the other 13.48.

The rainfall is greater in the foothills and mountains than on the plains. I never looked into the question as to what the precipitation at Lake Cheesman is. Loveland proper is about the center of District No. 4; perhaps a little West of the center. I do not claim that the average rainfall at Boulder is characteristic of District No. 6. Boulder is situated at the extreme western edge of the irrigated area in that district.

Redirect examination:

A quotation is made from Bulletin No. 45 relating to losses from reservoirs by evaporation (exact quotation in original tran-
668 script), in substance that the net loss would be the sum of the above losses from seepage and from evaporation, diminished by the rainfall, a combined loss which may be considered as a depth of six feet in one year.

Recross-examination:

Said bulletin also states: "If the loss from seepage is not more than two feet per annum, the site may be considered as practically water tight." Most of the reservoirs discussed in that paper are, of course, earth reservoirs.

Said paper also states that evaporation proceeds when the water is frozen, but at a diminished rate, averaging about one to one and a half inches per month. My factors of evaporation for the winter months, used in Exhibit 45, are higher than that.

The paper also states that the lower temperature of the water at high elevations, and the lower dew points, tend to decrease the evaporation; that the winter period is longer at the high elevations; that for the whole year the evaporation is in all probability considerably less at the high elevations than at the low ones; that evaporation is lessened by any influence which diminishes the wind or decreases the temperature of the water; that the deeper the lake the cooler the surface, consequently the less evaporation. I agree with all of those things, and that they are characteristic of Lake Cheesman, except that there is generally a fresh breeze up and down the canon.

Redirect examination:

I have no idea that Lake Cheesman is frozen over in November and December of every year, and in January and February and March. Large bodies of water maintain higher and more stable temperatures in winter than small bodies of water.

GEORGE M. BULL, a witness for the defendants.

Direct examination by Mr. Nye:

Civil engineer since 1897; a graduate of Rensselaer Polytechnic College, of Troy, New York; followed his profession since that time, mostly in hydraulic work; lived in Colorado since 1906; first worked on the Erie canal, then with Chicago and Northwestern, then be-

came deputy city engineer of Troy, assistant engineer on construction of new water works for Troy, New York State Barge Canal, in charge of design of structure for the Champlain division; with J. G. White & Company, and came to Denver with that company.

669 Was chief engineer for the Denver Reservoir Irrigation Company; since then have been in general practice; in 1906 principal part of work for Denver Reservoir Irrigation Company and J. G. White was examining and reporting on different propositions on the Platte river and surrounding watersheds; collected and preserved data in connection with the work, and preserved same in permanent file.

Has since added data as the result of work with the East Denver Municipal District water supply; is generally familiar with the water system of the Denver Union Water Company, and has visited Cheesman Lake; has taken reports and data regarding storage possibilities on South Platte river, relating to conditions of irrigation at present, and has gotten out certain estimates, using records of the state engineer's office, commissioners' and state reports.

Witness prepared Exhibit 37, which is topographical map of the South Platte river in the vicinity of Denver; the notations in red were put on specially.

The general limits of irrigation districts 8, 2 and 1 are shown by the red line crossing the river. The second plat in the exhibit shows records of precipitation at Denver between 1872 and 1911, made from the records of the weather bureau, and shows departure of precipitation from the normal, in per cent.

The broken black line in the month of April is not considered; it was put on for another purpose. The next plat shows three things: the amount of storage in Lake Cheesman during each month of the years between 1900 and 1913, the average monthly flow during each month, and the time of the greatest flood volume during each month.

At the left of the diagram is a storage curve showing the elevations above the bottom of the reservoir at which various volumes of water are stored. The portion marked "storage capacity in use" shows the draft on the reservoir, and was prepared from official records in the state engineer's office.

The table in the middle of the diagram shows water for various calendar years that entered the reservoir, and is the summation for entire year of what is shown below in the pink-tinted portion. The mean supply entering Lake Cheesman for the period is 118,400 acre-feet; this mean is not used in connection with this case. Witness then describes the next chart, which refers to ditches, in the order of location, from Platte Canon to Cache la Poudre, giving various data regarding priority of each ditch and prior appropriations

670 from which can be determined the location of ditch, the decade of its priority, approximately the volume, and how much is decreed ahead of it; the diagram was not prepared especially for this case.

The next diagram shows graphically how various floods along Platte river would be handled by various ditches covering flood water

months from 1905 to 1913; no month containing less than 700 second-feet flow shown.

By this diagram can be observed the lack of capacity or excessive capacity, and can determine readily whether there is water enough to fill certain ditches during certain floods.

(Exhibit 38 marked for identification.)

Shows water supplied the English High Line between 1901 and 1913, compared and checked with water commissioner's records. The year 1902 not platted because of lack of records; secured the records of the High Line from Mr. Wall.

Witness further describes Exhibit 38.

Exhibit 39 marked for identification. The first table shows witness' conclusions as to the amount of water available for storage in each year in each month of the year, from 1901 to 1913, inclusive. The red figures are a correction. Had no data on 1914.

Made an effort to show all character of operations of Cheesman lake as an irrigation supply, on 40,000, 50,000, 60,000 and 70,000 acre-foot bases; further describes Exhibit 39.

Describes Exhibit 39.

In his studies has treated the year as being a calendar year from January 1 to January 1; explains Exhibit 39.

Explains Exhibit 39.

Exhibit 39 does not graphically show the months when the water would go over the spillway, or the amount in the various months; that must be told from witness' notes; further describes Exhibit 39.

Describes Exhibit 39.

Exhibit 40 was prepared to show comparative relibility of Cheesman storage irrigation water right, and various other irrigation systems along the Platte. Describes Exhibit 40.

Figures on acreage, water supply and water duty taken from the Commissioners' reports in various years on file in the state engineer's office; has added the entire acreage in the various years, and divided by the number of years, and done the same thing with the water, thereby getting mean water supply and mean acreage and mean duty. No records for the years 1901 and 1902; with regard to "Water Supply in Lake Cheesman" and "Departure in Lake Cheesman," witness simply transferred the tables over from the computation.

Describes Exhibit 40.

671 Describes Exhibit 40. The duty charged to Lake Cheesman water in the Burlington table is the duty shown by actual application in the Burlington supply. Obtained the information as to crops raised under the Brantner ditch from the state engineer's office.

Determined that the Lake Cheesman supply, for a system operated like the Burlington ditch, would irrigate 25,300 acres, arrived at by taking the gross supply in Lake Cheesman, without any deduction for loss in transmission or evaporation, and dividing that gross supply by the duty of water; this amount would be reduced if proper deductions for transmission and evaporation were made. The elements of transmission and evaporation are not taken into consideration in the tables in Exhibit 40. Applying the Brantner duty to the Lake Cheesman supply, the acreage irrigable from the Chees-

man supply would be 15,300, and the same treatment is given the tables for the Fulton, Brighton, Farmers Independent, and Hewes & Cook ditches.

In the table referring to comparison of Lake Cheesman storage supply, with the maximum annual draft of 60,000 acre-feet, in the existing irrigation systems along South Platte river, during a period from 1901 to 1913, the ditches selected in preparing the diagram were the only ditches of any considerable acreage in district 2, and represent a range from the Burlington, with the poorest right, to the Brantner, with the oldest rights. Witness considers these ditches typical. Further describes Exhibit 40.

Describes Exhibit 40.

The Brantner ditch has the best record and the Burlington ditch the worst of those described. Cheesman supply departs next farthest from the normal, than the Burlington ditch; all the other ditches depart less from the normal, and are more uniform than the Cheesman supply. In these determinations witness used as a period eleven years, because have no records for the first two years; data secured from the records in the State Engineer's office.

Explains Exhibit 40.

In preparing the tables in Exhibit 40, witness aimed to determine the monthly and yearly supply available for storage at Lake Cheesman, and the relative reliability of the supply for irrigation purposes. Witness assumed that Lake Cheesman had a right to store 79,064 acre-feet any year when the supply was available to be stored in that lake, and that the reservoir had the right to carry over as much of that supply as was desirable and still store its maximum capacity, if available, for the next year; relied upon the com-
672 pany's record as to supply coming into the reservoir, and that the amount coming into the reservoir was the gross amount from which the storage could be obtained; and assumed that the records of the Antero reservoir, showing the storage there, were correct; and that the records of the English High Line were correct, and that the records of the water commissioners, showing the ditches that received water during each month of the irrigation season, and the last ditches that were receiving the water, was a correct statement as to the ditches shut down and the ditches that were receiving water, Placed all these records in the same category, and used them. Assumed that when any senior appropriated water in districts 8 or 2, was not available, that Cheesman had no right to store water.

Considered the English High Line, with a priority of 1879, at the head of district 8, as the limiting ditch; it irrigates approximately 22,000 acres of land. In district 2, considered the Burlington ditch as the limiting ditch, with a priority of 1885; irrigates 15,000 to 17,000 acres, and takes out of the river above all streams of perennial flow in the district. These ditches are at the head of irrigation in their respective districts. The High Line irrigates a total of 27,000 or 28,000 acres directly from the river, and the Burlington has under it about the same amount as the Brantner and Fulton; assumed that when these ditches, having a senior priority to Cheesman, were not receiving a water supply and needed it for irrigation, Cheesman had no right to store.

Exhibits 41 and 42 marked for identification. Exhibit 41 states witness' conclusions as to various months and years as to water supply for storage in Cheesman. Also conditions of irrigation along the river on various days and months. Exhibit 42 is a part of 41, which, for convenience, is put in a second volume.

First four pages of Exhibit 41 explain method used in obtaining the estimates that follow.

Goes back and explains Exhibit 40. Percentages of departure for duty of water in Brantner ditch is taken in terms of the duty of water. In Cheesman it is taken on the percentage of the water supply. Wishes to make a correction in Exhibit 40.

Witness then takes Exhibits 39, 41 and 42 and explains relations. At commencement of Exhibit 41 explains the use of exhibits.

Repeats testimony as to original data or records used in computation. In months where there has been water available during part of the time have taken records to determine what was available and equated it to the supply entering Cheesman. When all
673 ditches were receiving water supply and there was an excess of water entering district as shown by water commissioner's reports, have given Cheesman the entire supply entering the lake.

Have examined records of actual storage at Cheesman, and have often used the records of actual storage as limiting condition. Defines boundaries between districts 23, 8 and 2. High Line ditch is a limiting ditch in district 8, the Burlington canal the limiting ditch in 2; two canals have aggregate of 35,000 acres of land, and supply to these ditches shows clearly available storage in Cheesman. The extension of High Line canal for East Denver district, 60,000 acres, is shown. O'Brien canal is a joint canal with the Burlington for three miles. The original Burlington had capacity of 350 second-feet. The enlarged joint canal has capacity of 1250 second-feet. At bifurcation of two ditches three miles below intake, O'Brien canal has capacity of 900 second-feet, leaving to Barr lake for part of its capacity for Standley lake, and extends in a smaller canal to the Henrylyn district. O'Brien canal has not been adjudicated, probably 1904 or 1905, subsequent to Lake Cheesman. O'Brien canal runs on higher grade than the Burlington and permits enlargement of Barr lake, which has been enlarged to a capacity of 34,000 acre-feet. Its original capacity was 11,000 acre-feet. Division between upper and lower district 2 is where St. Vrain joins the Platte. It is the division used by the division engineer for convenience.

Graphical precipitation charts made from weather bureau reports for study in general way. Use of water often depends on rainfall. Further describes Exhibit 39.

Further describes Exhibit 39 as previously described.

No flood diagram for 1908, because there was no flood in that year. Used the flood diagrams in studying the question of storage. Takes June, 1907, as illustration, and knows that there was 1700 second-feet for one day.

English High Line and O'Brien canal could have taken the whole flood. The flood diagrams are not arranged in order of days, and

would not tell the days on which the floods took place, nor does the flood diagram, where it shows a certain flood for more than one day, mean that those days were successive.

Further explains diagram in Exhibit 39.

Further explanation of Exhibit 39. Used Exhibit 38 constantly to show condition of water supply in the High Line canal.

Further explains Exhibit 38. Further explains Exhibits 41 and 42.

674 The records in the office of the state engineer from 1905 to 1913 are full and explicit as to what happened in the way of ditches securing water from the Platte river. The records between 1901 and 1905 are very meagre. During latter period, must resort more to what was actually done in way of storage at Lake Cheesman and what was actually supplied to English High Line to form principal basis of estimate. Illustrates use of exhibit in the following way: "You will note in Exhibit 39, the first table, the table showing the estimate of volume of storage of water supply of the south fork, the estimate that has been allowed for 1901 for Lake Cheesman, the total volume being 63,220 acre-feet. On page 108 of Exhibit 42 you will notice in the first paragraph the general condition of run-off during that year, as shown by the records of Lake Cheesman. They were about 93 per cent of the normal run-off. The next paragraph is noted the precipitation for that year, and its departure from the normal, which is in tabular form for those quantities. During the months of January, February and March, the records for water supply entering Lake Cheesman show that the volume coming into the reservoir was 890 acre-feet, 840 acre-feet, and 4170 acre-feet, respectively. These are all estimated as being available for storage in Lake Cheesman. During the month of April there entered Lake Cheesman 11,900 acre-feet. The English High Line canal diverted 5000 acre-feet, and it is estimated that in this month the entire supply that entered Lake Cheesman was available for storage." Witness then explains the same thing by using the month of May.

Illustrates table by explaining application of month of June. Same illustration for June and July. Illustrates month of August, September and October. In October, High Line could not have used full supply if it could have gotten it, and so storage was allowed in Lake Cheesman.

Nothing in the diagram indicates that condition. It is merely a matter of opinion. Had no records of the Burlington ditch, and so allowed storage of 3600 acre-feet. All November and December storage allowed, making total of 63,220 acre-feet for the year 1901.

Records are more positive in 1902, but gives that year the same treatment as 1901. The year 1902 was a year of very low stream flow, and the High Line received only 5000 acre-feet, all, practically, in the month of April. Months of January, February and March are all estimated as available for storage, and all the water entering Lake Cheesman in those months was allowed. No stor-ge is estimated for April, because of the meagre supply that the High Line received; and there could have been no storage during April, May,

June, July, August, September, October and November.
675 Witness explains tables as to 1904 in Exhibit 42.

Corrects Exhibit 42, page 97; changes 3680 acre-feet to 2680. Continues explanation of treatment of year 1904.

Continues explanation of 1904.

Continues explanation as to 1904, and begins explanation of 1907.

Continues explanation of 1907.

Takes up September of 1907 and explains what his exhibits show with reference thereto. Where notes refer to a ditch as the last ditch receiving water, it means that it is the latest priority receiving water.

Wherever reference is made to a ditch receiving water, it is meant that it is the last ditch. Fulton ditch has four different appropriations. One is No. 21 in the '60s. Farmers Independent, one appropriation No. 23 is in the '60s. The exhibits do not give the date of priority of the different ditches. Witness takes that from his notes.

The earliest priority of the Fulton ditch, dated May 1, 1865, was receiving water September 21, 1907. Continues explanation of treatment of September, 1907.

Treatment of remaining months is exactly the same. Begins explanation of treatment of 1911.

Continues explanation of 1911.

April 15, 1911, the Last Chance ditch of April 3, 1865, was the last ditch receiving water. April 22, the Brown ditch of December, 1862, was the last ditch drawing water. April 29, the Brown ditch was the last ditch receiving water. During April, in district 2, on April 1, the last ditch receiving water was the Farmers Independent, of November 20, 1865. On April 8, the Meadow Island ditch, of May 3, 1866, was the last ditch drawing water. On April 15, the Farmers Independent ditch, of November 20, 1865, was the last ditch receiving water. April 22, the Farmers Independent, November 20, 1865, was the last ditch drawing water. On April 29, the Farmers Independent ditch, of November 20, 1865, was the last ditch drawing water. No water could have been stored in Lake Cheesman during April. Witness continues, giving in similar detail for the remaining months of 1911.

Only flood period in 1911 occurred in July, due to melting snows. About 3000 acre-feet were stored in Cheesman during this month, but this was immediately turned out, together with an additional 1000 acre-feet. Operations at Antero did not affect storage. During July High Line drew a full supply of water, but this included
50 second-feet of storage. On July 22nd there was 300
676 second-feet of storage water being sent down from district 23.

Witness then proceeds to describe the conditions in July, 1911.

Gives priority of Brantner, Burlington and Fulton ditches. Continues to describe conditions on the stream and the use of water in the month of July.

Continues explanation of treatment of the year 1911.

Continues explanation of conditions in 1911.

Turning to the year 1913, the precipitation for that year is referred to in the notes in Exhibit 41.

Diagrams of precipitation made two years ago. 1913 was 130 per cent of the normal precipitation. Month of December, that year, was 870 per cent of the normal, due to very heavy snow.

The year would have been below normal in precipitation except for the December snow. The year 1913 fairly normal for the entire period of time. That year it was 103 per cent normal at Lake Cheesman, and at South Platte, for both forks, about 112 per cent of the normal. This latter figure would be changed slightly, due to the storage at Lake Cheesman.

There were no large flood months in 1913. Largest flood passing Denver was in June, 1913; would have only amounted to 1650 second-feet, and the largest flood coming out of Platte Canon was a little less than 1500 second-feet. Peak floods in that year not as large as in a great many years. Have no record in 1913 for the High Line supply. There is nothing abnormal about the year.

Witness details treatment of the year 1913 from his exhibits 39, 40, 41 and 42. Gets figure for the High Line for that year from the figures of the water commissioner.

Exhibit 37 shows that water went over the Cheesman spillway from April until June of 1913. Witness continues to describe treatment of the year 1913 in detail.

Continues treatment of the year 1913.

Allows 3470 acre-feet available for storage in September, 1913, by taking the excess of water supply in district 8, according to the commissioner's reports, and allowed Lake Cheesman that amount as entering the reservoir, first reducing it to acre-feet, and that equalled 3470 acre-feet.

Witness is now describing the method used in determining the years 1901 and 1902 where the records were incomplete, 1902 being a year of short flow, and the year 1904 one of short supply, the year 1907 was a large year; 1911, a short year; 1913, a normal year. 1913 was normal so far as run-off was concerned, but below normal in actual storage supply. This shortage of storage supply
in 1913 due to condition of stream flow in the river during
677 various months. Nothing peculiar about the treatment of other years to which attention should be called.

Gave each year the character of treatment mentioned, and final conclusions appear on first blueprint sheet in Exhibit 39. Witness again describes Exhibit 39 and the second blueprint sheet showing his treatment of the different assumed drafts upon Cheesman reservoir.

Considered that assumed draft at 10,000 foot intervals covered all the practical limits necessary. Witness then proceeds further with his explanation of the assumed draft.

Water which goes over the spillway would be lost, but a record of it is a factor as an element showing the inefficiency of certain conditions of operation.

Continues explanation of operation of reservoir by his assumed draft of 40,000 acre-feet.

Continues explanation of 40,000 acre-foot draft.

Explains 50,000 acre-foot draft.

Continues explanation of 50,000 acre-foot draft.

Gives explanation of tables showing operation of 60,000 acre-foot draft.

Explanation of 70,000 acre-foot draft.

Maximum departure above the mean for the 60,000 acre-foot draft was 118 per cent; which is 138 per cent for the 70,000 acre-foot draft, but is as low as 23 per cent in the year 1903. There is more average water supply conserved for the 70,000 acre-foot than there is with the 60,000 acre-foot draft, but a much less efficient service, because there are many more years of deficiencies than occurred under the 60,000 acre-foot draft. In using 70,000 acre-foot draft, you are attempting to deliver more water in some years than is necessary to conserve the entire supply; consequently you are delivering too much water, and the 60,000 acre-foot draft will accomplish the same results with a more regular supply. Witness will make slips to be added to the exhibit showing percentages of the assumed draft that can be delivered each year, rather than the departure from the mean draft.

Witness explains 70,000 acre-foot draft based on Comstock's estimates of available storage. This draft might be possible on Comstock's estimate of available storage, but not on the witness' estimates.

Witness compares results of 60,000 acre-foot draft on his own and Anderson's estimates of available storage.

Witness thinks that for general irrigation use 60,000 acre-foot draft would give largest supply and reasonably good service. For the range of years from 1904 to 1914, assuming a loss in the average year for evaporation of 2000 acre-feet, the average draft
678 would be 48,440 acre-feet. Determined evaporation from various data; determined from the curve of the capacities on the diagram at what height in each month the water in the reservoir would stand. Took the acreage on the flow line of the reservoir corresponding to the various heights, and applied the evaporation coefficient and used for the month, thereby secured evaporation for each month and a total for the year; first deducted 18 inches rainfall from computed evaporation; deducted the average evaporation and arrived at an average yield of 48,440 acre-feet, starting with a full reservoir in 1901. On this draft there would be five years within the period when the reservoir would furnish less than 60,000 acre-feet. Made no evaporation estimates for the 50,000 acre-foot draft.

Between the year 1901 and 1914 the gross supply on 60,000 acre-foot draft would be 50,600 acre-feet average. The supply would vary from 23 to 138 per cent of the average quantity.

Further description of Exhibit 40, with reference to the comparison of the Cheesman storage supply on a 60,000 acre-foot draft with the various ditches shown on Exhibit 40.

Witness reaches percentage of departure used on last mentioned diagram in following manner: Took from records in state engi-

neer's office the acreage irrigated under the ditches used for comparison in the various years; then divided the volume of water annually diverted in acre-feet by the number of acres irrigated. This gave duty of water. The summation of all the annual duties divided by the number of years would give the average duty. By dividing the duty for a certain year by the mean duty for the period of years, gives a percentage which represents the period of departure of each annual duty from the mean.

In preparing the tables in question, evaporation was not included. If it were considered, it would reduce the 50,860 acre-feet to 48,680 acre-feet, 2000 acre-feet being deducted for evaporation, and corresponding changes would have to be made throughout the table.

In arriving at the acreage irrigable by the Cheesman water, witness divided the mean supply by the average duty of water. All the tables in Exhibit 40 are fully explained by the charts whereon the comparisons between Cheesman lake supply and the various ditch supplies are made.

Explains the charts.

Explains the charts of the Fulton, Brighton, Brantner and other ditches. The second set of charts makes the same comparison and illustration, using Mr. Anderson's estimates. The object of
679 making the comparative studies was to show in a practical way how the regularity of Lake Cheesman was supplied as estimated by witness Bull and Mr. Anderson, compared with existing ditches of size on the Platte river, and includes a consideration of how this sup-ly is distributed throughout the years.

The ditches selected represent the old water rights, with the exception of the Burlington. Witness recites priorities of the Brantner, Fulton, Brighton, Hewes & Cook, and Farmers Independent ditch, as shown on his exhibit.

These ditches represent the larger systems along the Platte river in district 2 and the best water rights on the stream in that district. The acreage under those ditches is not as large as that under the High Line. There are only 5000 acres, in addition to the lands under the High Line, which are irrigated in district 8.

Crops under the ditches selected for comparison are about the same as those under the High Line. They are on both sides of the river. On a 60,000 acre-foot draft Lake Cheesman will yield an average annual supply of 48,880 acre-feet, arrived at by deducting 2000 acre-feet from 50,860 acre-feet, as shown on Exhibit 39.

To determine proper draft on Lake Cheesman witness started with gross estimated supply, less evaporation of 50,860 acre-feet then made various studies of various drafts; in attempting to assume an operation on a 40,000 acre-foot draft it had a loss of 10,000 acre-feet over the spillway. On a 50,000 acre-foot draft there was a loss of 6000 acre-feet over the spillway, thus sacrificing average delivery to uniformity of delivery. On 60,000 acre-foot draft, it would reduce the loss over the the spillway to a minimum; and in taking 70,000 acre-foot draft no better results could be obtained; no greater saving of water, and a reduction in efficiency; so concluded that

greatest practical mean supply that can be delivered is 48,460 acre-feet on a 60,000 acre-foot draft.

If reservoir capacity was greater, could reach ideal condition of being able to deliver average supply every year. Explains column of percentage of maximum draft in Exhibit 39.

Tables show 85 per cent efficiency of delivery on the assumed operation of 60,000 acre-feet; no allowance for evaporation.

Averages evaporation at 2000 acre-feet per annum; it might be 1000 or it might be 3000 in different years.

The average supply from Lake Cheesman would be 48,860 acre-feet. In presenting water rights in Cheesman to a purchaser it would have to be stated that there was an average supply of 48,860 feet, and that some years it could deliver more and some
680 years less. That amount of water could not be delivered every year without enlarging the reservoir.

Witness does not enter into the question of the value of the water right. The maximum amount that could be delivered unfailingly each year from the reservoir would be 40,000 acre-feet. This would be at a loss of 10,000 acre-feet every year. The efficiency of reservoir water depends on its distance from the land where it has to be used for irrigation. As supply of reservoir water diminishes in regularity, water rights would decrease in value. Witness has given no consideration to the question of value. Studies have been confined to volume and efficiency.

Knows the character of the Platte river and the soil through which it flows. It follows a valley one to two miles wide, underlain by a bed of gravel; the same down into district 2. Has given consideration to the question of loss by seepage. On that question there is a variety of opinion.

Can only tell what the exact loss would be by actual experience. Describes causes of seepage.

Four to five per cent of the total volume of Lake Cheesman would be lost from Denver to Platte Canon. Thinks that in the operation of Lake Cheesman ten per cent would be lost from the lake to the place of application.

Made some studies concerning carriage of water through the High Line canal to the East Denver Municipal District; and determined the loss in transit in an enlarged High Line canal, would be forty per cent in the canal itself.

Making this determination, considered the size and kind of ditch, kind of structures; the fact that the old ditch had to be enlarged and the bottom cleaned and the present seal of the ditch broken, and the entire ditch would be like a new ditch, and the water would have to be carried clear to Denver before delivery on the land. The loss by seepage would be a diminishing quantity as the ditch becomes sealed. Is an engineer on a ditch in the San Luis valley, where it is estimated thirty per cent as final loss. Whether a reservoir supply is better than direct flow depends entirely on the reservoir and what is the direct water supply. The terms direct water supply and reservoir supply, themselves, do not mean anything. Two elements enter into the value of a reservoir water supply; Capacity of the

reservoir to control its supply and the supply to fill the reservoir. Knows of reservoirs that don't get any water at all, and other instances where the reservoirs are not big enough to control the water. Every reservoir has got to be considered by itself, both as to volume and regularity of supply, and in the same way the direct ditch you speak of has got to be studied, because it may
681 be a late priority and have no water, or an early priority and have water all the time.

The difference in value between a reservoir that has a water supply that constantly keeps it full, and one that has a supply that is only a percentage on the mean of the total capacity of the reservoir, is this: In one case you have got your average supply equal to the capacity of the reservoir, and the other you have an average supply that the capacity of the reservoir will control under conditions of each year's volume that is furnished. If the supply is bigger than the reservoir, the reservoir cannot control it. If the reservoir furnishes the capacity full every year, why, it is a constant supply. The only way to determine the value of the reservoir supply of Cheesman lake, in view of the fact that it has never been used for irrigation purposes, is to compare it with existing water rights of similar character and efficiency, and determine what will be the average water supply delivered from it.

How often are you going to get that supply? Will you get it every year or get a great deal more one year at the sacrifice of the next year? That is, what is its regularity of supply? The delivery on an average of 48,860 acre-feet in such a way that some years you will deliver 60,000 acre-feet and some years 48,860 acre-feet creates an element of weakness.

The lack of capacity to control the supply makes a sacrifice of efficiency to maintain average. Taking an old existing water right like the Brantner, which has the first right on the river, it has two elements of value, just as a reservoir has two elements of value. That is the amount that it can deliver under its priority and its amount of the regularity of the supply. It makes a difference whether the Brantner ditch furnishes a sufficient supply to the first of June, affording 3 acre-feet before the first of June, and thereafter is short of water. Reservoir water can be readily compared with the direct-flow right in regularity and volume of supply, and storage rights used for irrigation create the same kind of values that a direct-flow right does. The O'Brien canal could carry the annual Cheesman supply without enlarging. The only other ditch that could approximate it would be the English High Line, but it would need enlarging.

The O'Brien canal has filled on the flood waters of the Platte river for storage in the enlarged Barr lake and several reservoirs of the Henrylyn district, a distance of 25 or 30 miles.

Water carried from Cheesman lake to Barr lake and re-stored would lose from evaporation and seepage. In measuring duty of water witness has measured the duty at the headgate, and in-
682 cludes both the loss in the ditch and the water applied on the land. Witness in his tables has used the duty with reference

to the gross water supply the system consumes, measured at the headgate.

Witness' comparisons show comparative volume and comparative regularity of the flow as between Cheesman reservoir and certain ditches, and incidentally shows what similar volume and similar regularity of flow is required to create values in the locality. You have a comparison of volume and regularity and comparative data as to what volume and regularity have done in the way of creating values.

In other words, it is data that one having an expert knowledge of the value of water rights may use in reaching conclusions as to value.

(Thereupon an adjournment was taken.)

Witness has considered Standley lake, East Denver district and Henrylyn; all systems depending on combination of direct flow and storage.

In district 8, the East Denver Municipal district has a development of an extension from the English High Line canal for lands lying to the east and north of Denver, east of Barr lake, some 60,000 acres under the system. The English High Line has been enlarged and the extension to take in the 60,000 acres, north about as far as Barr lake. Several reservoirs contemplated in connection with it; district contemplated to secure storage from the Antero. Next system is Henrylyn district and Standley system, involving enlargement of Burlington ditch, construction of new ditch to Barr lake. Approximately 35,000 acres under the Standley-Barr lake system; 60,000 acres under the Henrylyn system. Barr lake has been increased from 11,000 to 34,000 acre-feet. Denver reservoir has constructed the Milton reservoir, filled from a canal from Platte river at Platteville; holds 40,000 acre-feet; 10,000 acres under the reservoir; filled through the Milton canal. Flood water control of Clear Creek through the Cook canal to Stanley lake has been an added development. Small reservoirs spoken of in east Denver district are distribution reservoirs.

Henrylyn, Barr Lake and Standley lake systems have been operated for some time. East Denver Municipal district has never completed construction of canal; no practical irrigation been under it. Milton lake system is active, and the Standley system is active from Standley lake; water from Clear creek; been more or less operation under the O'Brien canal since it was constructed. Some of these would use flood waters from the Platte river. Antero reservoir has been constructed in district 23, and will store 40,000 acre-feet, but the system has been constructed for much larger capacity. Lost Park reservoir has a claimed capacity of 17,000 acre-feet.

683 The approximate cost of the development mentioned is four or five million dollars in bonds. The last work was done on the East Denver Municipal district last year.

Witness has made a study of the Brighton, Fulton, Brantner, Farmers Independent and the Hewes & Cook ditches.

(And thereupon document Exhibit 43 was produced.)

Witness has examined water commissioner's weekly records from

1905 to 1913, inclusive (there being no records on file prior to 1905). Witness has compiled in Exhibit 43 the data from those water commissioners' reports showing when water would be cut off from the various ditches in question, assuming that when Lake Cheesman could be supplied these ditches could be supplied. This is done and set down in Exhibit 43, to show whether in connection with the old ditches in district 2 there are long periods of time when no water is available for them.

Continues explanation of Exhibit 43.

In considering available storage at Lake Cheesman, witness did not consider water company's claimed right to 66 second-feet continuous flow during the winter months for Platte Canon ditch, and assumed that during the winter months all water entering Lake Cheesman was available for storage there, and that none was necessary to supply the Platte Canon ditch.

If there was not 66 feet available above the Platte Canon ditch, water would have to be deducted from the storage at Lake Cheesman or from the 66 feet stored in some other place; it could not be stored in two places. Studies of the old ditches bring out the regularity of the water supply, the use and duty of water to secure the degree of cultivation that crop growths and conditions in these various districts require, and afford a comparison for new lands. For example, if 3.3 acre-feet per acre is necessary under the Brantner ditch, and we attempt to put this supply on similar lands, with an additional length of canal to serve the land, it is a fair indication of the water which must be supplied to get the same results. Cheesman lake water, if used for irrigation through an extension of old and existing systems, should not be counted on for higher duty than that shown by the old ditches, approximately 3.3 acre-feet to the acre.

In any canal system, if the canal required 3.3 acre-feet per acre and the Lake Cheesman supply was purchased to furnish 1 acre-foot of land, it would have to bear its similar proportion of loss in connection with the total supply required, as the rest of the ditches—it would lack just as much. There would be no higher duty for the Cheesman water unless canals were rebuilt so they could
684 handle water more efficiently. Exhibits 37 to 43 introduced in evidence, and Exhibits 41, 42 and 43 as being Mr. Bull's detailed testimony on the matters referred to.

Cross-examination.

By Mr. Dorsey:

Witness' testimony confined to study of the quantity and regularity of yield of Lake Cheesman. Witness determined this in the following manner: whenever witness determined that the High Line ditch, at the head of district 8, and the Burlington ditch, at the head of district 2, were not receiving an adequate supply of water, no storage was allowed to Cheesman; this method modified somewhat by consideration of other ditches, but witness' general assumption was that when direct rights in district 8 or 2 prior in time to Chees-

man could not receive water for direct irrigation, Cheesman would have no rights to store. The High Line ditch is the latest ditch in district 8 prior to Cheesman, and the Burlington ditch is the latest ditch in district 2 prior to Cheesman.

If the Burlington and High Line ditches were receiving an adequate supply, witness determined whether any of the South Platte water at Cheesman was necessary to furnish that adequate supply to the two ditches, and credited Cheesman storage with whatever South Platte flow at Cheesman was not necessary for such supply; for example, assuming that the commissioner's reports for a given period would show 500 feet in district 8, 300 feet in district 2, and that 200 feet would be excess over the direct flow demands of the ditches considered, and if an inspection of the record of the supply entering Lake Cheesman showed 200 feet at that point, the entire 200 feet excess would be credited to Cheesman.

Witness explains that in one month there was more water entering district 8 than was required therein, and there was no demand for the excess in district 2; therefore he took a period of two weeks and equated this with the amount that was flowing into Lake Cheesman, and took it for a number of days. If he had taken the minimum flow and equated it, it might have been in error.

On many occasions witness considered the actual storage at Lake Cheesman and allowed that storage in his estimates of assumed storage. Thinks this was done in one or two cases where there was just enough direct flow to supply the ditches prior to Cheesman in the two districts,—this on the theory that if the storage actually made in Cheesman were allowed to flow down, it would make an excess in the two districts. Witness did not assume any uniform proper demand in districts 8 and 2, but each week took the reports of the water commissioners as showing demand for that
685 period, and applied the water commissioners' reported demand rather than witness' estimated demand, taking water commissioners' statements at their face value and allowing Cheesman to store such part of the excessive flow over and above the water commissioners' demands as was found to be flowing in the South Platte at Lake Cheesman.

Water commissioners' reports not complete from 1901 to 1905; for those years witness relied upon storage records at Cheesman, High Line records and precipitation, and similar records; during that period allowed whatever was actually stored in Cheesman as proper storage; thinks that actual storage made by Cheesman in 1904 was the determining factor for that year. Knows of no case in years 1901 to 1905 where any possible storage was allowed in addition to what was actually stored in Cheesman, but determination for those years is not based entirely on actual storage at Cheesman; considered also the High Line records.

Cannot say whether in the years 1901 to 1905 Cheesman was allowed any possible storage in excess of actual storage; considered High Line records, and knows that from 1901 to 1905 Cheesman was in course of construction, and actual storage there could not have been an accurate guide.

Using year 1902 as a criterion for the period, witness illustrates that he considered record of precipitation and record of the High Line, showing that it received no supply, practically, except in April, and drew his conclusion as to possible storage from that data.

Began to use water commissioners' reports in 1905, the earliest year they were available. Years considered by witness can be divided into two groups: 1901 to 1904 without water commissioners' reports, 1905 to 1913 with water commissioners' reports. Detailed testimony confined to years from 1901 to 1913, but refers to 1914 as a complete year. In considering years 1901 to 1904, the practical method was to deny Cheesman storage whenever High Line canal was not drawing water.

Did not necessarily follow that Cheesman could store when High Line was drawing water; that question depended on the quantity the High Line was drawing. In the years 1905 to 1913 used the weekly reports of the water commissioners; used data of water company for inflow at Cheesman; commissioners' reports, which would show the quantity of water coming out of the canyon, and from Plum Creek and Bear Creek, and seepage; the demands of the district, and the statement of the last ditch receiving water, and notes in regard to general conditions of irrigation. Accepted these reports at face value; had no other data; accepted records on file in the state engineer's office in regard to Antero and Cheesman, and the commissioners' reports were the best data on the matters covered by them.

686. Did not investigate volume of stream flow further than the water commissioners' reports; assumed storage at Cheesman would be limited by amount flowing in south fork at that point. Emphasizes fact that nine times out of ten governing factor as to storage in Lake Cheesman is what ditches were and what were not receiving water supply. It is only occasionally that the flow cuts much material figure in what could be stored at Cheesman; as a rule, there is either feast or famine.

The commissioners' weekly reports show last ditch receiving water on date of report, and do not give the respective ditches of latest priority receiving water on intermediate days, but ditches are not opened up and shut down often enough to justify consideration of that variation. It takes time to change the gates of the various ditches to utilize variations in flow. Witness has not considered periods of half-day's storage, but takes a practical period, or considered any period of excess flow or short flow which was not long enough to permit regulation of ditches in accordance with the change of flow.

Witness gives example of reservoir in southern part of state, which is watched every day by deputy water commissioners, who regulates the use of the water in the reservoir and reads the gauge every day; when a peak flood of two or three hundred acre-feet comes into the reservoir, he orders it turned out to the ditches below which are not receiving water.

Ordinary floods that have occurred in the years from 1905 to

1913 would not be large enough to fill all the dry ditches receiving no water supply below Cheesman; this is shown by mass diagram relating to floods. It makes a difference whether, at the time a flood comes, there are a large number of ditches prior in point of time to Cheesman and entitled to take the flood, that have been dry for a long time, or whether such ditches have been reasonably well supplied with water prior to the flood, in considering the capacity of such ditches to take and use the whole flood.

It might occur that prior to a flood the ditches had been fairly supplied, and part of the flood would be available for storage in Lake Cheesman, and the water commissioner's report, made a few days subsequently, would not record the condition; and in this respect there is a considerable range of possibility; such occurrences would not be covered by witness' determinations; such floods might possibly have actually occurred.

Thinks water commissioner's reports are accurate and that the division engineers accept them.

Did not consult the division engineers' independent table of gaugings of the stream flow, or make a detailed comparison
687 of the water commissioner's statement of stream flow with the hydrographic data on file in the state engineer's office, or the reading of the gauges appearing on such data.

The first blueplint in Exhibit 39 shows available water in South Platte which could be stored by reservoir at Cheesman under Cheesman's priority, and in the tables which follow it the gross volume of Cheesman supply is shown, which is limited by the actual capacity of the reservoir; and column 7 in the tables of exhibit 39 is comparable with pla-ntiff's exhibit A-31, which is Mr. Anderson's estimate of storage in Lake Cheesman, limited by the storage capacity of the reservoir, but Anderson includes 1899, 1900 and 1914.

No material difference in respect to available storage for the comparable years between witness and Anderson, except for years 1911 and 1913. Witness compares in detail differences between storage allowed by Anderson and by himself during comparable years. Witness' average annual storage is 48,548 acre-feet; Anderson's storage for the same years is 53,729 acre-feet, or a difference of 9.6 per cent; the big difference appearing mainly in the years 1911 and 1913. The year 1914 is not included in the averages in the tables. The addition of the years 1900 and 1914 would increase witness' averages.

Witness' average, including 1900 and 1914, would be 52617 acre-feet, less 2000 acre-feet for evaporation. Mr. Anderson's averages for the same period would be 57,107 acre-feet, or a difference of 7.8 per cent.

In plate 4 of exhibit 37, diagram 2, the adjudications to the different ditches are arranged chronologically; in diagram 1 the ditches are arranged geographically, in order of place but not of distance. The English High Line appears as adjudicated priority No. 69, quantity 1184 second-feet, but by note it appears that capacity of ditch is 600 second-feet, or practically half of adjudicated priority.

The respective capacities of the Burlington and Evans No. 2 ditches are greater than their adjudicated priorities, but these ditches have been enlarged for the new systems served by them, and the additional capacities are now being adjudicated. All additional capacities are subsequent to Cheesman, and principally for storage.

In district 2, the total adjudicated priorities are 3800 second-feet, and the actual capacity of the ditches is 3400 second-feet. The original Burlington had an adjudication of 350 second-feet, and practically that capacity.

There are other ditches than the High Line which have decreed priorities in excess of capacity. That ditch has the largest adjudicated priority of any considered. Did not have in mind any
688 particular quantity of water that would be necessary to satisfy High Line or Burlington.

Witness would consider that if commissioners' statements showed 600 second-feet entering the district, and that 400 second-feet were required for district 2, and that the High Line was taking 200 second-feet, and the same sort of condition existed in district 2, he would assume that while the ditches were getting water they were getting all they needed, and that Cheesman might store all or a part of the south fork water. For further example, if 100 second-feet more were coming into the district than were needed, and there were 100 second-feet going into Cheesman, would allow Cheesman to store 100 second-feet, but if only 25 second-feet were coming into Cheesman, that would be the limit of its storage.

Requires the Burlington and High Line ditches to be supplied and an excess in districts 8 and 2 before allowing storage at Cheesman, except that by considering amount actually stored at Cheesman flow can be corrected as though Cheesman were not there. If Cheesman stores, and there was still an excess, that excess is added to actual storage to get possible storage. Storage at Cheesman is limited by the excess over and above the demands of these two ditches and by the actual flow in south fork at Cheesman.

The excess would be determined by the water commissioner's report as to the water flowing into his district over and above the amounts stated by him to be the needs of the canals; those reports taken at face value; unless such an excess existed, no storage permitted at Lake Cheesman; such an excess must exist over the demands of both districts 8 and 2. If the commissioner's reports show that the needs of the canals in district 2 were greater than the quantity of water entering the district from all sources, that would mean that Cheesman could not store. When in such reports it is stated that there is an excessive demand over supply, priorities of that district will be cut down, and the statement of excessive demands over supply is always borne out by the further statement that ditches of earlier priority are the last ones getting water: districts 3, 4, 5, 6, 7 and 9 are also tributary to district 2; they all lie west of the Platte and cover tributary streams. The superintendents of the ditches which are shut down make demands upon the commissioners, and this automatically corrects excessive demands in tributary

districts. These demands for water must be supplied as far as possible from tributary districts.

Witness assumes that when a ditch is not drawing water that it needs it and cannot get it. There may be times when a
689 ditch does not want water and would not take it, but when a ditch is dry for a long period of time and earlier ditches are not getting water, it indicates that that ditch does not get water because it cannot.

If a ditch is drawing less than its decreed priority, it ordinarily indicates shortage of water, but not necessarily; for example, if the English High Line is taking 100 second-feet and there is an excess of water in the district, and they could have taken 550 second-feet, it indicates that they took all they wanted and did not need a full supply. Has considered such conditions in estimating storage at Cheesman, but witness' notes as set forth in exhibits 41 and 42 would show what he has done in that respect.

Witness has not used a sweeping statement that a certain amount of water was necessary for the direct flow ditches, but has considered records of each month by itself; does not believe in such sweeping statements. If the High Line was taking 600 second-feet, witness would have no doubt that it was fully supplied; if it was taking less, witness would consider the particular conditions at that time. Ditches may have been taking less than their decreed priority, and yet be taking to their capacity, but that point does not enter, practically, into consideration of Cheesman storage. There might be 15 or 20 or 30 priorities shut off between the Burlington and the High Line, and that would show the water conditions in the district; the individual statement of one ditch would not cut much figure in the conclusion. Witness' notes show actual capacity of different ditches to divert.

If the difference between decreed priorities and capacities operated to great extremes, it would probably affect the situation. There are one or two priorities listed on the chart which have no existence. There is nothing particularly important omitted from chart No. 4, exhibit 37; there might be some small ones which are unimportant. Plate 5 of exhibit 37 shows the flood months; this plate gotten up to study general effect of flood in the river, and there was no use working out diagrams for months that had floods less than 700 second-feet, the point being whether or not certain floods would be so large that the ordinary ditch would not control. Thinks floods less than that could be taken care of by the ditches. Data for floods taken from geological surveys.

The records of the Geological Survey show gauges at Denver and gauges at South Platte taken daily. Gauging stations have been run differently at different times—some by Geological Survey of the United States, some by the state engineer, and some by corporations.

The flood diagram is made up from stream flows, day by day,
690 showing marked changes in stages of the river occurring in short spaces of time; some considerable changes within periods of 24 and 48 hours; these changes do not show chronologically on that chart.

Chart does not show at what time of month particular flood occurred or at what time it existed in respect to any other particular stage of the river. No floods in excess of 700 second-feet in 1908 or 1910, and only in the month of July 1911, and that month the raise was pretty uniform, from 400 second-feet up to 1200 second-feet. As compared with August, 1909, there were some extreme rises; in the latter month changes came in comparatively small intervals of time. The diagram shows whether variations are far apart, but does not show, day by day.

Flood diagrams show graphically what ditch capacity such a flood would have satisfied; that aids to determine whether the flood should be allowed to pass Cheesman.

Has not checked up the commissioners' semi-weekly reports. In the case of the reservoir in southern Colorado, referred to by witness, the deputy commissioner at the reservoir knows the needs of the ditches down-stream; when small floods come and are impounded, he is ordered to turn them out the next day, if needed; that is the Cucharas reservoir, of the Pueblo Rocky Ford irrigation system.

The deputy commissioner is constantly informed as to changes in the ditches below. Witness was, of course, not constantly informed as to changes that occurred during the periods between the commissioner's weekly reports, in considering the storage of floods. All witnesses are estimating on volume of water storable. If it were a matter of absolute figures, would all reach the same conclusion, and witness had no information except the water commissioners' report. The Cucharas reservoir is on a flood-water stream or creek. From the weekly reports of the Commissioners, there might have been a famine at the end of the week and a feast in the middle of the week, but witness has found no place where it was a feast. The last diagram of exhibit 37 shows some considerable floods, but they occur in months when the water supply is all available for storage.

Exhibit 38 was based on records obtained about two years ago from Mr. Wall, showing the High Line operation; should have stated in direct testimony that he had no records of river flow for 1901, but has such records for 1902; did not see the record of river flow for 1901, but there is such a record, and also one for 1902;
don't know whether they are in the state engineer's office,
691 but they are in the Geological Survey. Referring to exhibit 39, showing total available storage in the south fork of the South Platte river for various years and months, as stated, the years 1901 to 1904 were based upon High Line diversion, precipitation records and storage at Lake Cheesman. If witness stated that years 1905 to 1913 were based entirely upon reports of water commissioners of districts 8 and 2, it was incorrect. In the period from 1905 to 1913 did not allow actual storage at Cheesman as available storage, unless the water commissioner's reports showed it was properly made.

In one month there was some question as to whether actual storage should be allowed, and witness allowed it; took actual storage into account, but it did not influence judgment.

So far as demands and requirements of ditches below Cheesman

were concerned in 1905 and thereafter, based conclusions entirely on the water commissioners' reports; that was the controlling consideration in making up mind whether storage at Cheesman should be allowed. Is satisfied that water commissioners' reports should be credited at face value. Commissioners are local men, appointed by local influence, but that is true of all the records used by the witness; did not use the United States Geological Survey records; thinks data as a whole is very good; would be true that water commissioner does not minimize the needs of his district in his reports.

The superintendents of the different ditches in a district do not let their water commissioner get far off from being fair; naturally a commissioner will do his best to get water to the people in his own district, and the superintendents in his district are urging him to get water, and he would be influenced by them rather than by the superintendents of ditches in districts that are trying to keep the water. Cheesman water would have to be transferred for use for irrigation.

It is more reliable to go back and say the Fulton ditch has got water than to go back to some abstruse proposition. The important factor in the commissioners' reports is the report of what ditches are taking water, and nine years out of ten the conditions in this respect are so clear that you can say that the real measurements are secondary to the working out of the system of whether the water was available or whether the ditches were going through.

Both districts must be considered before conclusion as to storable water can be reached. If High Line was getting 100 second-feet at a certain time and the Burlington was getting 200 second-feet, that would be one of the instances where it would be necessary to consider seriously what the commissioner says was the kind of water going into the district and the amount required, and his statement would be taken at face value, and that witness has done
692 wherever a similar condition arose, taking into consideration also precipitation and storage.

Referring to exhibit 39, blueprint for 1902 shows available storage to be 8340 acre-feet, and Mr. Anderson, by exhibits A-31 and A-32, shows available storage of 10,962 acre-feet. This was the lowest year under estimate. Only 18 to 20 per cent of the normal flow entered Cheesman; the total stream flow was about 28 per cent of normal.

Estimates storage in January, February and March of all the flow of the south fork, but in exhibit 37 allows no storage in April, 1902. The chart of actual storages appearing in exhibit 37 shows actual storage at Cheesman in April.

The 780 acre-feet of actual storage in that year was disallowed by witness. Page 106 of exhibit 42 shows the precipitation in April was only 29 per cent normal. On the High Line canal diagrams, it is shown that that ditch got 100 second-feet most of the time and 40 second-feet for the month. It would not take long to store 780 acre-feet in Cheesman, but some ditches must have been shy. In 1902 ditches took water in April; water commissioners' reports show that all the ditches through both districts start taking water about

April 1st, and in dry years some of them start in March. Has not looked up division engineer's reports to find when and in what relative quantities water is diverted by direct irrigators in the month of April; imagines it would be about 5 or 7 per cent for the month of April.

There is not so much demand for irrigation in April. Does not think that the fact that the High Line was drawing 100 second-feet in April indicates that it had all it needed. Thinks ditches are likely to demand all they need.

Sometimes a demand upon Lake Cheesman to turn out stored water would not be promptly complied with, but cannot say that that was in April, 1902. It would have taken about three days to store 780 acre-feet. Has not the records to show varation in flow of the South Platte at the intake of the High Line during the early days of April, 1902. The supply at the headgate of the High Line at the beginning of April was 125 second-feet; there were three or four days at the beginning of April, 1902, when the High Line did not divert any water, although it had diverted a little in March and began to divert again about the 3rd of April, during which time the water in the river rose 25 second-feet. This would indicate to witness that someone else wanted the water. About the 4th of the month there were 30 second-feet taken by the High Line; this continued until there was a 600 second-foot flood in the stream;
693 the canal then took 100 second-feet, and after the peak flood went by, it took 40 second-feet; and then there was another peak flood of 550 second-feet, and the canal diversion rose to 100 second-feet, and the flood went down, and the canal was cut down to 40 second-feet; another peak flood followed, and the canal diversion went up to 75 second-feet, and then down again, and then was cut off. This is conclusive evidence to witness that canal was being regulated on the flood. The fact that 100 second feet was all the High Line needed during peak floods does not indicate there might have been storage in Cheesman. Although the supply in the stream was rising during the first three or four days of April, the High Line took nothing, but it must be considered that there are nearly 250 second-feet of ditches in district 2 of earlier priorities than the High Line; is inclined to think that the demands of these ditches cut off the High Line. Demands of the earlier ditches may have ceased when the High Line began again, and diverted 40 second-feet.

The hydrograph for year 1902, in exhibit 38, shows that the flood in the river at the High Line intake rose to a rate of 600 second-feet. The demands upon that 600 second-feet for direct flow rights might vary in different years; that was one of the principal reasons for using monthly method instead of considering some arbitrary rule.

Exhibit 38, hydrograph relative to year 1902, shows that later in the month of April the stream rose to a rate of 575 second-feet, and between the two high flows mentioned it rose to 450 second-feet, but witness thinks that during those periods ditches were limited

to the amount taken by them. About 1500 acre-feet was sored in Lake Cheesman in October and November (exhibit 37).

Witness has not allowed it. As a mathematical statement, the addition of the storage actually stored in Cheesman at times when no storage was allowed by witness, to the storage allowed by witness at other times—the difference between witness' estimate and Anderson's estimate for the year would be practically wiped out. Witness did not allow November and December storage, because the High Line, with 20,000 acres under irrigation, had no water in May, June, July, August or September; in October it had about 200 acre-feet, and in November 500 acre-feet. There were some heavy rains, as shown by exhibit 42, page 105; that rainfall was 370 per cent of normal, but that rainfall would not take care of the fact that the district was burned out for five or six months, and irrigation water would have been needed in October and November. In the year 1911 witness allows 9690 acre-feet storage, as shown by exhibit 39, and Anderson allows 29,544, as shown by exhibits A-31 and A-32, or a difference of 19,854 acre-feet in that year.

694 In 1911 witness allows entire flow of South Fork to be stored in January, February and March. After the month of April, there is no storage until November. Witness referred to page 1959 of the transcript of his testimony, and to page 27 of exhibit 41, and corrects testimony to read that 4,000 acre-feet was stored in the Antero up to May 1st.

The 4,000 acre-feet so stored in Antero should be added to the storage in Lake Cheesman during the winter months. On page 25 of exhibit 41, the September 1912 storage was overestimated 6,000 acre-feet, so witness did not make correction for the additional 4,000 acre-feet in 1911.

It would not be fair to compensate a mistake in a short year like 1911 by setting off against it a mistake in a plenteous year like 1912.

The fact, shown in exhibit 41, page 27, that there was a withdrawal from Cheesman during the months of January, February and March, 1911, of approximately 4,000 acre-feet, leaving 1,000 acre-feet at the beginning of the year, is not significant, and is merely relative information.

The withdrawal of 4,000 acre-feet from Lake Cheesman during the period mentioned might account for storage of 4,000 acre-feet at Antero.

Witness' statement on his exhibit "Thus accounting for the storage of supply in Antero" not necessarily correct. At any rate, does not affect the storage available for Cheesman. The withdrawal from the Antero and the storage in Cheesman at the time in question have no relation one to the other, so far as witness knows.

Witness will have to correct exhibit 39 for storage in those months in 1911 when there was actual storage in Antero. Exhibit 41, page 28, shows there could have been no storage in Cheesman during April, 1911, and exhibit 39 allows no storage for that month.

There was some storage in Lake Cheesman; did not investigate whether there was storage in Antero; Antero storage would not appear in the stream flow. Notwithstanding actual storage at Chees-

man and Antero, witness did not allow it because of the water commissioners' reports.

Highest flood in April, 1911, was 150 second-feet, or 300 acre-feet each 24 hours. It would take 3 days to produce 858 acre-feet. Water commissioners' records show a drought through the entire period. In June, July, August, September and October, 1911, no storage allowed on exhibit 39; that is based on the water commissioners' reports.

During that period storage actually occurred at Lake Cheesman in considerable quantities. Witness did not estimate it as avail-
695 able storage. There was also storage in October, which was not allowed; based estimate upon water commissioner's report and correspondence in the state engineer's office with regard to the storage in Lake Cheesman; correspondence referred to is exhibit No. 36.

From a consideration of the water commissioner's report, which the witness gives in detail, witness justifies that conclusion.

According to witness' statement, water commissioner's reports show that the Burlington ditch received no water during the month of July. Page 32 of exhibit 41 shows that in the month of July, 1911, the only flood period of that year occurred, and that is shown upon the diagram, exhibit 37. Copy of water commissioner's report for July 1st, was read to witness, showing that the Burlington ditch ran water July 4, 7 and 8.

Witness explains matter of 4,000 acre-feet storage in Antero.

The supply in May, 1911, should have been 3,400 acre-feet; the supply for May, 1910 should be reduced 6,610 acre-feet, and on an assumed draft of 60,000 acre-feet, this would necessitate the correction of the amount carried over at the end of the year 1910 from 19,420 acre-feet, as given, to 12,802 acre-feet. The storage of 4,000 acre-feet at Antero includes 500 acre-feet stored in April, but there was no storage water available in April, it was not legitimate storage; does not consider the change sufficiently material to carry it through the tables. Originally estimated 6,610 acre-feet as possible storage in May, 1910, but now finds it should not have been so estimated. Cannot tell what the error was; thinks it was in reading commissioner's records.

The first table in exhibit 39 is inaccurate as to the possible storage in May, 1910, of 6,610 acre-feet, and lacks 3,400 acre-feet in May, 1911. Commissioner's report for July 1, 1911, as read to witness on page 2138 of his testimony, was correct, and the Burlington ditch did have water on those dates.

Witness thinks that report indicates that the Burlington ditch wanted water at that time and was not allowed it. Report contains no statement of the amount actually diverted by the Burlington on the days mentioned.

The hydrograph of Lake Cheesman contained in exhibit 37 shows that storage actually occurred in the month of June and July, 1911. Exhibit 41, page 32, shows that in June and July, 1911, about 6,000 acre-feet was stored in Cheesman, and turned out beginning about the 15th of June.

According to the records of the company, 4,912 acre-feet were stored from the 15th to the 20th of June, 1911, and 6,430
696 acre-feet from the 3rd to the 8th of July, and the 22nd and 23rd of July, making a total of 11,342 acre-feet. The hydrograph in exhibit 37 shows the total storage of something like 7,000 acre-feet. The withdrawals occurred between July 8th and 22nd, at the rate of 635 acre-feet per day, or a total of 9,363 acre-feet.

The water commissioner's reports show that from 100 to 120 acre-feet per day were withdrawn for the company's uses. Witness' assumption that Cheesman had no right to store this amount based upon general conditions along the river and correspondence in the state engineer's office. Did not consider one more important than the other. Made no examination of flows of the stream at Platte Canon, day by day, early in July, and on the 22nd and 23rd of July, when the storage occurred.

Witness examines Mr. Comstock's exhibit A-53, and knows what is meant by, "Stream flow corrected for Lake Cheesman." From that exhibit it appears that the stream flow at Platte Canyon was 1,612 second-feet; that on July 5th it was 1,607 second feet; July 6th, 1,556 second-feet; July 7th, 1,373 second-feet; July 8th, 1,327 second-feet; July 9th, 1,091 second-feet; July 22nd, 1,007 second-feet; July 23rd, 1,032 second-feet; assumes those figures to be correct. Referring to the last diagram in exhibit 37, it appears that after correcting flow at Denver for needs of district 8, the gross flow was 900 second-feet for one day, and for a number of days it was something like 800 second-feet, and then continually diminished until for the entire month there was 350 second-feet flowing in the stream. The total water supply passing Denver and entering district No. 2 was possibly 35,000 acre-feet, and there was in district 2 nearly 3,400 second-feet actual ditch capacity to use this water. This has a bearing on the question. In the diagram in exhibit 37, the flows in 1911 should be corrected by adding the actual Cheesman storage.

Whether these floods were needed for beneficial purposes in district 2 depends upon the report of the water commissioners. Referring to the water commissioner's report of July 8th, 1911, it appears that on that date there were 1,530 second-feet entering the district and 650 second-feet required. There was no unsupplied need in district 8, and storage was going on in Lake Cheesman.

In district 2, on July 1st, 1911, there were 680 second-feet entering the district, 1,200 second-feet required; water commissioner's report on that date was, "This is Monday morning. A good general rain in this district July 2nd, conditions relieved."

697 It appears further on exhibit 41, page 33, that in district 2, on July 8th, 1911, there were 1,290 second-feet entering the district, 1,200 second-feet required, Brantner Third Enlargement was taking water. From this it appears that notwithstanding Cheesman was actually storing at the time of these reports, district 2 was also fully supplied.

It appears that for the week ending July 8th, 1911, the Burlington was drawing water part of the time, and there was more water in the district than was needed. There are periods of perhaps a day or

two where, under strict enforcements, a ditch might have been shut down or opened up, but that period is too short for practical administration of the water. Places will be found where, according to the records, districts 8 and 2 were so short that Cheesman should not have stored, but witness assumed these conditions relieved before it was necessary to cut Cheesman off, and has assumed that in flood conditions, for a period of a day or two, all the water would be required in certain districts.

For a certain day there might be an apparent additional supply, but the next day would show a striking shortage. Does not think Cheesman had a right to store in July, 1911; the flood would spread out and Cheesman would not have a right to store, if the flood could be used by prior ditches down the river.

Witness estimates some storage at Cheesman at times when it would not technically be proper, and this balanced the disallowance at other times when storage would be technically proper.

Witness thinks that in certain periods where storage automatically occurred, there would be reason for regulating it and turning it out the next day if the district had needed the water; for the question arises whether water can be stored which, if allowed to flow down the stream, would on the next or succeeding days reach ditches which would have need for it; this is not equivalent to saying that you cannot store on peak flood, for the peak flood may be so great that the ditches cannot use it. The propriety of storage is not to be determined as of the day when the storage is made, but the general effect of the flood stored on other water rights that might want to use it should be considered. A reservoir might be permitted to temporarily hold peak floods until conditions below were known. Thinks water would go from Lake Cheesman to district 2 in 36 hours, or two days.

There was no shortage on July 8th in district 2. There was a shortage on July 15th. Does not know exact day when the shortage began.

If the water stored in Cheesman on July 8th had been al-
698 lowed to flow down, it might have done good to some district below district 2.

Does not think storage should have taken place in Cheesman July, 1911.

Cannot say how long flood must continue or how large it must be in order to permit storage. Conceding that in July, 1911, the stream flow at South Platte ran constantly at the rate of over 1,000 second-feet for a period of ten days, and Cheesman was storing, witness does not think the storage was proper, for the Burlington got water for three days and had had no water since March.

Witness cannot say offhand how long the peak flood would have to run. Witness was referred to exhibit 41, page 59; based the conclusion that there could be no storage in October, 1911, on the fact that Burlington and the High Line were without water, as were other ditches in districts 8 and 2.

In that month 2,000 acre-feet were stored in Cheesman and 4,500 acre-feet in Anero.

Witness was asked whether, if High Line with its direct appropriation, owned the Antero, which had storage water, with priority sub-

sequent to the direct appropriation, it was probable that the High Line would permit the Antero to store water that was needed for direct irrigation; witness says that should not have been allowed, but officers of High Line may not have desired to deplete their storage for the benefit of their direct right users; the High Line management might not have advised their users; had they done so, the users would probably have made objection.

Cannot assume that anybody was trying to be dishonest; does not know why the water was stored in Antero, if there was a direct flow demand for it in the High Line. Witness had assumed that in October, 1911, there was an unsupplied need in the High Line.

The facts indicate that the High Line stored some of its direct flow in Antero.

Thinks the facts show that the High Line people preferred to store their water for use next season than to use it in October, 1911.

The fact that Lake Cheesman was storing at the same time might indicate that the High Line was ignorant of the conditions, or Lake Cheesman refused to let water out, or that the High Line had no use for the water.

The fact that Cheesman and Antero were both storing, does not show that High Line did not need water. The conditions in district 2 have something to do with it.

699 Insists that the English High Line, with 20,000 acres to irrigate, would need a water supply the last three weeks of August and in September.

Water commissioners' reports for September 30 and October 20 show that on latter date the district was supplied with water and the High Line was not drawing water.

The attention of witness was called to the fact that for nearly three weeks in the month of October commissioners' reports conveyed no information; the report for October 20th shows snow; the report for October 14th shows greater portion of water used for domestic purposes; report on October 28th in district 8 showed water used for domestic purposes; this indicates no special irrigation need; is not certain that there was any demand from district 2 to have water turned out of Antero or Cheesman. Weather conditions ought to be somewhere near the same in district 2 as in 8; the report of September 30, 1911, for district 2, shows heavy rains. The report of October 14th shows "ditches all closed between Monday noon and Tuesday night." No demand for water made in report of October 14th. Report of October 28th states "Weather has been cool and dry, with slight snow, and Burlington diverting 100 cubic feet per second for storage."

Other records not quoted show decided demands for water. For example, report of September 30, shows 430 second-feet entering the district; 1,000 second-feet required. The Fulton ditch, priority of 1865, the last ditch receiving water. The foot-note of the report says, "Heavy rains, Saturday night, September 30th, at Brighton and Platteville." On October 7th, the supply was 490 second-feet, and the demand was 800 second-feet, the Fulton ditch receiving water.

On the 14th the record is incomplete; has no information as to the 14th.

The report of October 14th, does show that 385 second-feet was coming into the district and 385 going out; this i-dicates no diversion. Ditches all closed between Monday noon and Tuesday night, October 9, 1910; indicates absolutely no demand for irrigation for three days. This is weekly report, and does not indicate demand for any time during the week; there might have been possibility of storage in Lake Cheesman during that period for a few days. On October 21, 395 second-feet were entering the district, 800 second-feet required, and the Fulton ditch was the last ditch receiving water; at the end of the month it was about a balance as between supply and demand.

Report of October 28th, shows that 100 cubic feet per second was being diverted for storage; did not note that on examining the report; the demands therefore relate in part at least to storage; the Burlington ditch has 350 second-feet capacity, and its storage right is
700 prior to Cheesman. If it could have secured the water, would have taken more than 100 second-feet. Barr Lake has storage right of 11,000 acre-feet, prior to Cheesman.

Did not know that Burlington storage was all completed before April of each year. Does not necessarily justify a conclusion that Lake Cheesman could not store.

The rate of flow into Cheesman during the month of October from the 4th to 10th was an average of 135 second-feet or 270 acre-feet a day, or practically 2000 acre-feet in the time.

The stream flow at Cheesman would have supplied 2000 acre-feet during the time when the water commissioners' records are incomplete.

Witness again admits correction of his possible storage for year 1911 as shown on exhibit 39, by adding 3400 acre-feet for Antero storage in January, February and March, which could have been stored in Cheesman.

There was storage in April of about 600 acre-feet, which should not be added; does not add the 2000 acre-feet stored in Cheesman and the 4500 acre-feet stored in Antero in the month of October, 1911, because the question whether Barr Lake was filled or not enters into it, and on November 1st, 1911, Barr Lake was empty, and they would store if they could.

Barr Lake has a right to fill the reservoir and make up whatever is lost by evaporation and seepage which is a very material amount in that reservoir; that reservoir leaks; adjudication gives them right to make up for loss by leakage. Thinks that Barr Lake decree would permit to store its original 11000 acre-feet, and if it all leaked out, fill again to capacity.

Barr Lake was filled at the beginning of the season and empty at the end of the season, and there was only 5000 feet of direct flow in the canal. It would not matter whether Barr Lake actually wanted the storage in October, for witness is estimating what under normal conditions Barr Lake could store.

Distinguishes between exceptional and normal conditions, and thinks that if Barr Lake was filled in the spring and empty in the

fall, and the owners were filling it again, that would be a normal condition; so, if Barr Lake was actually being refilled in October, or was being repaired and no water was wanted, witness would reject those conditions and substitute some condition appearing to the witness to be normal.

Understands that Barr Lake may make up any leakage from the stream. There is a loss in Barr Lake normally of 2160 acre-feet between January and April, and of 3000 acre-feet during the irrigation season, and from October to January 720 acre-feet, or in all 6800 acre-feet. The evaporation would be 2000 acre-feet per annum.

701 As witness interprets Barr Lake decree, it has the right to take from the river and store twice 11,000 acre-feet. In June and July 11,342 acre-feet was stored, and if that amount, added to the October storage, of 6500 acre-feet, and the correction of 3400 acre-feet for the winter months, were added to witness' estimates, it would make up the difference between witness and Anderson for the year. The year 1913 was normal as to runoff, and below normal as to storage supply; this is true as to main stream and tributary streams; as to the tributary streams below the mouth of the canon, witness was informed by the commissioners' reports; did not consider them for the purpose of determining whether normal or not, and did not investigate tributary streams for that purpose; has some notes on the effect on the stream flow of storages made and transfers of water from Antero and Cheesman.

20,500 acre-feet passed from Antero into Cheesman; 11,000 acre-feet was stored in Cheesman in July, August and September, 1913. Witness' attention called to this fact, and to page 11, 12 and 9 of his exhibit 41 for correction; there seems to be some confusion in exhibit 41 from using the Antero portion and the chart; there may be some mistakes in copying; has never had a chance to correct it. Got figures on quantity flowing into Lake Cheesman from the records in the state engineer's office taken by The Denver Union Water Company.

Does not know the details of how these records are taken, but understands there are gauging stations at each of the tributaries. Lake Cheesman is fed by the south fork of the Platte and by Goose creek coming from Lost Park, and by a creek called Turkey creek, of intermittent flow, and floods from dry water courses, and springs in the bed of the lake. Understands that the inflow is determined by readings on a gauge board, which shows changes in the level of the lake. Understands there are gauges around the lake, but thinks measurements at Goose creek and south fork should be controlled by the gauge of the lake heights, so that that is equivalent to a scale measurement.

It is impossible to measure separately all the various inflows into Lake Cheesman as a practical matter; the evaporation would not show on the gauge.

Counsel illustrates use of the gauge board, and witness says that by taking the different levels on the gauge board, the accretions to

the reservoir make up the evaporation before any increase is registered.

Evaporation should be added to the records of the total flow of the stream at Cheesman; makes no difference whether the water is running over the spillway. Hydrograph of Lake Cheesman in exhibit 37 shows that the level of the lake rose with com-
702 parative regularity until May, 1905, and it has been partically full all of the time since. This condition would give a maximum of evaporation, which would average something like 3,000 acre-feet per annum; to this should be added seepage from the lake. The question of seepage and evaporation is a new one to witness, and he is reluctant to answer without further examination.

In exhibit 39, table 3, showing method of handling Lake Cheesman on a 60,000 acre-foot annual draft, started January, 1901, with a full reservoir, and added month by month the volumes of storage available, wasting over the spillway whenever there was more than a full reservoir, and available storage which could not be made because of the full reservoir would be wasted.

The first large blueprint in exhibit 39 shows the 60,000 acre-foot annual draft; in the upper diagram that part is applied to witness' estimates of storage, and shows draft upon reservoir beginning late in May and continuing in June, July, August and September. This was done because other engineers estimated on the same basis.

Assumed the following rates of draft: 12,000 acre-feet in June, 24,000 acre-feet in July, 18,000 acre-feet in August, and 16,000 acre-feet in September; that method of draft assumes the use of the reservoir as a supplemental water supply; Changed the draft in the first year, thus making a saving of twelve or fifteen thousand acre-feet of water, which would mean a thousand acre-feet of the total supply for the mean time; the only place this makes a difference is at the beginning of the diagram. Explains further his table showing drafts. If the year 1914 is added to tables, the average draft would be increased to 51,546 acre-feet.

Witness does not include the year 1900, and has no records on it. He is prepared to assume that 1900 is a year of large flow. By including the year 1900 witness would have 19,064 acre-feet at the beginning of 1901, instead of full storage, but would have supplied full 60,000 acre-foot draft in the year 1900, and could have stored 32,600 acre-feet in the early months of 1901, which had to be wasted, according to witness' tables; and could have supplied the 60,000 acre-foot draft in 1901.

If the year 1900 was added, the average from 1900 to 1914 would be increased 2,110 acre-feet. Witness corrects his testimony given on page 2007, and states that he should have said that the average supply delivery of 50,860 acre-feet, with a maximum draft of 60,000 acre-feet, would be the most satisfactory supply. Does not wish to confound "draft" with the term "mean supply."

703 Intends to state that with 60,000 acre-foot maximum draft he would be able to deliver the largest average annual supply with the least fluctuations from the mean supply delivered, which is

shown clearly from the fact that with 70,000 acre-foot draft you are get-ing no more water supply but a more regular supply year by year. 60,000 acre-foot draft would give good service. Witness corrects previous testimony on page 2007 in which he refers to a range of years between 1900 and 1914, and says those years should include 1901 to 1914.

Column 8, 60,000 acre-foot draft table, exhibit 39, shows what is furnished out of the reservoir, and includes every year from 1901 to 1913, and those are the years averaged, and that average will be raised if the year 1914 is added.

The average on the draft of 60,000 acre-feet, if 1914 is included, would be 51,500 acre-feet, on the same basis as the tables, and if the year 1900 was added it would raise the average still more; and on direct testimony, when witness spoke of a period between 1900 and 1914 of an average of 48,440 acre-feet, after deducting 2,000 acre-feet for evaporation, he was referring to the years 1901 to 1913 only. Witness' evaporation estimate on direct examination was 2,000 acre-feet per annum; this evaporation estimate was based on fifteen hundredths of a foot in January, February and March, sixty-three hundredths of a foot in April; forty-eight hundredths of a foot in May; eighty-seven hundredths of a foot in June; sixty-nine hundredths of a foot in July; seventy-one hundredths of a foot in August; fifty-one hundredths of a foot in September; forty-one hundredths of a foot in October; thirty-five hundredths of a foot in November, two tenths of a foot in December. These figures refer to fraction of a foot, and are applied to whatever area the surface of the water had in any month or year. These are Signal Service Tables of evaporation; they are taken from various engineering reference books, and are standard tables. Thinks they were taken from Turneaure & Russell on Water Supply. The rainfall is deducted from the evaporation; taken out of the total for the year over the average surface. As to rainfall, took the average area of the year that the reservoir covered, taking 18 inches as an annual rainfall, and subtracted that from the total results of evaporation, and vertical loss would be 3.8 feet. Illustrating for the year 1908, the diagram shows in the various months the volume of storag.e From these volumes of storage can be ascertained the height of the water and the area of the surface; then, having the factor of area and factor of monthly evaporation,
reached the result. The unit of evaporation used was the
704 average for the month and the unit of surface was the average surface for the month; went through each year month by month. The average acreage for the year 1908 was 670 acres, the gross evaporation was 4,191 acre-feet, and the net evaporation 3,186 acre-feet. This was arrived at by deducting the rainfall from the gross evaporation.

Witness corrects his testimony; he is talking of 1907 instead of 1908, and all previous figures apply to 1907. The average acreage for each month in 1907 was as follows: 616 acres in January, 650 acres in February, 710 acres in March, 748 acres in April, 874 acres in May, 874 acres in June, 874 acres in July, 788 acres in August, 730 acres in September, 740 acres in October, 740 acres in November; 740 acres in December; took the end of each month;

instead of taking the average for the month, took the exposed surface on the last day of each month; this would not introduce any practical error. The average acreage for the year 1907 was 755 acres. Calculated an average acreage for each year in order to apply rainfall; has not all the tables.

Does not care to answer whether in the year 1901 part of the 32,600 acre-feet estimated as wastage could be used to take the place of evaporation loss.

In the year 1901 witness deducted evaporation, notwithstanding all the decreed appropriation had not been utilized and 32,600 acre-feet were wasted over the spillway, and still thinks that is proper.

Referring to exhibit 39, to the table based on the 60,000 acre-foot draft, and to column 8 thereof, and the percentages put in in red ink, for the period from 1901 to 1913, inclusive, there would be eight years of 100 per cent efficiency, one year of 95 per cent efficiency, one year of 87 per cent efficiency, one year of 59 per cent efficiency, one year of 43 per cent efficiency, and one year of nineteen and one-half per cent efficiency; 1903 was the low year caused by the low supply in 1902 and 1903. By including 1900 and 1914 there would be a period of 15 years with ten years of 100 per cent efficiency, instead of 8 years, as in the period previously considered.

(Witness was not permitted, over objection of defendants, to give his opinion as to effect of efficiency on value.)

On the 60,000 acre-foot draft a supply of 100 per cent in ten years out of 15, 95 per cent in one year and 87 per cent in another, is good service. (Witness not permitted to answer whether such an efficiency would be equivalent to full performance or not.)

Taking the full 15-year period, from 1900 to 1914, the average delivery from Cheesman reservoir would be 52,110 acre-feet,
705 without deducting evaporation, or an efficiency of 87 per cent; after deducting evaporation, of 2,000 acre-feet, the efficiency would be 83 1-3 per cent. Witness does not know the efficiency in operation of irrigation reservoirs in Colorado.

(Witness not permitted to answer whether on such efficiency as stated purchasers would be found for a supply of such efficiency on 60,000 acre-foot draft.)

Witness has concluded that the estimate of stream flow should be increased by whatever the loss by evaporation and seepage from Lake Cheesman would be.

Witness was asked whether such additions to the stream flow would give greater available storage, (which was objected to by defendants aand overruled); states that the addition of evaporation would increase the available storage. The reservoir was practically full between May, 1905, and the 1st of June, 1908.

The addition of evaporation would increase all of witness' estimates of storage supply.

It would be necessary to work through each month in actual detail to tell how much the increase would be.

Witness further discusses treatment of evaporation in reference to annual deductions for evaporation.

Witness' tables in exhibit 39 are all worked out without consid-

eration of evaporation, and has not testified as to what effect upon the average draft the matter of deducting evaporation would be.

Taking tables on 40,000 acre-foot draft, exhibit 39, column 8, showing an average delivery of 40,000 acre-feet, witness would not deduct evaporation from that amount; witness does not apply evaporation to the average draft, or that it ought to be deducted from the annual delivery on the 60,000 acre-foot draft.

To apply evaporation to the witness' tables, it would be necessary to go through the charts, figure out evaporation month by month, and apply it back for several years. Evaporation would have to be deducted from the theoretical amount of water in the reservoir, as shown by the tables, and witness has not determined what effect such deduction would have upon the deliveries, and thinks would not justify a deduction of 2,000 acre-feet from the average shown at the bottom of column 8 in the tables in exhibit 39.

The rainfall is a large factor in determining net evaporation, as is also the time of year when the surface of the water is exposed; to get a close result, must consider evaporation month by month.

It would have led to more accurate results if the precipitation had been considered month by month. Applied rainfall factor
706 to the average area in each year separately. Assumed rainfall at 18 inches annually. Witness did apply rainfall at the end of the year and got an average annual area, but did not have an average area for the series of years.

Witness cannot say whether in the actual operation of Lake Cheesman evaporation has been taken care of in the gross figures which appear in tables relative to storage, because the high points and low points might make a big difference.

It would be necessary to go through month by month to make the computation; evaporation must be determined month by month; rainfall could be determined month by month.

After determining evaporation, the stream flows into Lake Cheesman must be corrected to show the total available storage, assuming that the records of inflow do not show the entire flow; does not know exactly what the difference would be; it would be whatever the loss in evaporation was; it might be 2,000 acre-feet, but is making some computations to determine it.

The notes from which exhibits 41 and 42 were made were prepared before exhibit 39 was made. Witness worked out each year by itself before combining them.

Witness noticed the error of 3,400 acre-feet in the first three months of 1911 before counsel inquired about it, and after exhibits 41 and 42 were put in form; also made an error in respect to month of May, 1910, and carried it into tables in exhibit 39 by crediting 6,610 acre-feet which should not have been allowed; the error discovered on rechecking notes; does not know which one was discovered first.

The error in May, 1910, was discovered before exhibit 41 was completed, for it is referred to on page 43 of exhibit 41.

Witness carried over 19,412 acre-feet from 1910 to 1911. If the supposed mistake of 6,000-odd acre-feet in May were deducted, it

would leave approximately 13,000 acre-feet. In 1911 there was delivered out of the reservoir 25,712 acre-feet, and at the end of the year 3,390 acre-feet was carried over. Witness would deduct 6,610 acre-feet from the deliverable quantity, because the last three thousand acre-feet of supply secured during the year came in the last three months after the reservoir was empty.

Witness concludes that he did not discover the mistake as to January, February and March, 1911, until upon cross-examination. Does not recollect on what basis originally arrived at the estimate of 6,610 acre-feet storable in May, 1910, as per exhibit 39.

Witness changed his mind about this storage after looking over the commissioners' records for the two water districts. Witness does not know what other witnesses have testified to about storage in
707 May, 1910. Witness' attention called to fact that Mr. Field's estimate of storage for May 1910 was 6,612 acre-feet, or approximately witness' original estimate, but witness states that he never saw Mr. Field's estimate.

The records of Antero reservoir for the month of May, 1910, show actual storage of 500 acre-feet; witness corrects this and says it should be 1,000. Whether this was allowable storage would depend on the water commissioners' report. On May 7th water commissioner reported as to district 8, that the needs were supplied. High Line was drawing 300 second feet. Footnotes: Weather for week has been cold. Condition of district for irrigation, ground wet.

Read all reports through. Did not refer to the notes on May 7th. Commissioner in district 8 reported that Burlington ditch was drawing 225 second-feet, 200 second-feet of which was storage; does not know what priority the storage was being made on. There is nothing to show that on the reports: storage might have been diverted for a priority older or later than Cheesman. Witness considered that the storage was being diverted for an older priority.

Report of Sunday, May 1st, says, "Weather for week has been rain." Report for May 7th, showed 770 second-feet coming into the district, 570 second-feet used for irrigation and 200 second-feet for storage, and the commissioner reports the needs of the district to be 850 second-feet.

It is possible that this need was for storage purposes, and if it was for a later priority, it would not affect the storage at Cheesman, and it is impossible to tell from the report whether the storage was desired on an early or a later storage right than Cheesman's; nevertheless, witness reached conclusion that Cheesman could not store during the month of May, and that the actual storage made during that month should not be allowed.

During the week in question 4,000 acre-feet flowed into Cheesman, and according to one interpretation of the water commissioners' reports, the whole thing could have been stored, and to this might be added a thousand feet that was stored in Antero that week. Witness' exhibit 41, page 43, should be corrected to read, "From this the conclusion is drawn that there would have been no supply available during the month of May, 1910."

Exhibit 40 is supplemented by exhibit 43. Exhibit 43 contains tables introduced for the purpose of showing reliability of the various

old ditch systems, and such other data as would be necessary to make a comparison of those systems with Lake Cheesman; comparative regularity of the supplies of a reservoir, on the one hand, and
708 a ditch system on the other, may be determined and the requirements of irrigation, as shown by existing systems, can be determined; these things are shown by the tables.

In comparing a reservoir supply and a ditch supply, there is a factor which has an important bearing on the relative value and relative efficiency to such sources which is entirely distinct from reliability in respect to furnishing the same total quantity each year, and that factor is whether you are getting the water with practical regularity; and the element of time when water can be delivered is an important element. If the High Line could take 740,000 acre-feet in April and not get any water after that, it would not be as valuable as a 40,000 acre-foot supply in the reservoir which could be delivered at any time.

Whether a direct flow right would have the flexibility of a storage right would depend upon the characteristics of the two rights compared. A reservoir which could get nothing out of the river would not compare with a direct flow right which did get some water. If we compare a ditch that is able to deliver 40,000 acre-feet during the season with a reservoir which has that much stored and is able to deliver it at any time during the season, the ditch being able to deliver only at such time and in such quantities as the water flows into the headgate, the reservoir supply would have the additional feature that it might be used for partial supply for the system. Cannot say whether that is the way reservoirs are usually handled. All witness had to do *with* have been part of a combined system of direct flow and storage, and have been used to balance the direct supply. A reservoir supply might be used either way.

There is usually sale for irrigation water at some price. All conditions being equal, reservoir water used as a supplemental supply would have its highest efficiency and perform its highest service, but whether it would have the highest value would depend upon local conditions.

There is certain demand for water around Denver; whether it is a demand from people who have money to pay for it witness does not know. There is a great deal of land that ought to have complete water supply. There must be demand for supplemental supply. Has examined reservoirs that were to be used for supplemental supply, and upon the assumption that demand existed for storage water in the vicinity of Denver, but witness' reports thereon have been made for complete supplies.

The Burlington represents a ditch of very intermittent and very poor water rights. There can be no comparison between such a ditch and the Cheesman supply; that comparison was used
709 by witness to show the limits of ditches that had a poor supply.

On an assumption of an annual draft of 60,000 acre-feet, witness had average annual area of exposed surface of water in Lake Cheesman of 432 acres; this covers whole period from 1901 to 1913.

Witness gives years beginning with 1901. The net result of witness' computations was an estimated net loss of 3.8 feet per annum; on that basis witness gets average annual exaporation of 1341.6 acre-feet, but by correcting from month to month, gets 2000 acre-feet. Some months evaporation factor was much greater than others, and if there was more area in those months it would make a corresponding difference in the total amount of evaporation; then there would be greater rainfall in some months than others.

Exhibit 40 shows that from the year 1903 to 1913, inclusive, the Burlington diverted an average of 2 acre-feet per acre; this does not show at what time in the year the water was diverted through the Burlington; in the year 1912 the Burlington is shown to have diverted twice the average amount of water per acre. Witness understands this represents diversion under the adjudication.

There was apparently less average in 1912 than in some other years; might possibly be true that large diversion through the Burlington in 1912 was for the purpose of irrigating increased acreage; 1907 was a high year for the Burlington; water commissioner's report does not give purpose of diversion through the Burlington ditch. Witness does not know whether water commissioners' reports show that the Burlington diverted 20,450 acre-feet in 1912, and that the remaining diversion was for storage. Witness explains his charts in exhibit 40, having reference to comparative supplies of Burlington ditch and Cheesman storage.

The purpose of the comparison between Cheesman supply and Burlington ditch was to show the great differences, the flexibility of the Cheesman right as compared with the Burlington, rather than to prove that the right was as good as the Burlington. The comparative chart shows the great departures from the average deliveries which are in themselves proof of the flexibility. The table does not exhibit on its face the relative power to deliver all the water or the major part of it at times when it is really needed, which is the characteristic attribute of a reservoir, as distinguished from a ditch, and witness had no intention of trying to show that the Burlington right was comparable in value with the Cheesman right.

As to the other comparative tables in exhibit 40, it was the intention to show how direct flow ditches compare with the Cheesman right. These comparative charts and the table in exhibit 40 show the relation of the quantity of water developed per acre irrigated to the average quantity of water developed per acre irrigated as shown at the foot of the column, or is, in other words, a percentage of duty. The percentage shown in exhibit 40 with regard to Lake Cheesman is a percentage of water supply and delivery.

710

The percentages in red on exhibit 39 show the efficiency of Lake Cheesman from the point of view of actual annual delivery; did not consider that percentage at all in exhibit 40.

Has not considered whether reservoir supply could be sold on a basis of an average delivery of 50,860 acre-feet with the understanding to the purchaser that in ten years out of fifteen he was going to get 118 per cent of the average supply. Witness has had con-

siderable experience in irrigation business. Water might be sold on several bases; reservoir water might be sold on a basis of 60,000 acre-feet, purchaser knowing that at certain years he would get less water, or you might sell it on lower average basis and assure the purchaser of a more certain supply. It is an actual fact that irrigationists attempt to sell on the highest delivery that can be made for a reasonable number of years, and the price varies with their ability to make delivery.

In speaking of a guaranteed supply, witness meant that you might give purchaser guarantee of what the supply would be—that is, guarantee an efficiency of 85 per cent of what was purchased, or 100 per cent; does not know of any systems that are handled on a basis of 100 per cent guaranty; on an assumed draft of 60,000 acre-feet, Lake Cheesman would have an efficiency for a period of 15 years of 85 per cent, and in ten out of those fifteen years it would have an efficiency of 100 per cent. That is a very good efficiency. Has investigated no other reservoirs comparable with it, so cannot say and does not know whether there are others.

As shown by exhibit 39, witness contemplates draft upon the reservoir as follows: 20 per cent in June, 40 per cent in July, 30 per cent in August, 10 per cent in September. That is predicated upon use of the reservoir for supplemental supply, otherwise there would have to be a draft in April, May and a small draft in September provided for. Witness has undertaken to make a comparison between a reservoir supply with a draft confined to the months of June, July, August and September, with a direct flow supply furnished from April to November in varying amounts.

This is a comparison of the water right as used in connection with furnishing the entire supply for a system. It does not take in the item of possible additional flexibility. You might hold it
711 back and deliver it all in any specified month. It is simply considering it from the standpoint of how it would develop there an entire irrigation system, as compared with a direct right. The tables are based on a consideration of Lake Cheesman as a sole source of supply, and is of no value as far as the matter of supplemental supply from Cheesman is concerned.

Does not think that a reservoir supply is more efficient than any direct supply can be. It depends upon what special reservoir is being considered, and what special direct supply. The use of water is affected by rainfall. The greater the rainfall the less need of water for irrigation purposes; and during a rainy month, all other things being equal, less direct flow water would be needed. If your water supply was impounded in a reservoir, it would not be necessary to draw on it for that month, but if water supply was direct flow, it must be used that month or permitted to flow down the river, but witness does not think this demonstrates greater efficiency of reservoir supply, because a direct flow ditch does not necessarily use its efficiency when the water for a certain month goes by, because if the right is an early one, there may be water the next month to satisfy demands.

Assuming a direct flow which can always be supplied, and a total

draft of 40,000 acre-feet per annum made, and comparing it with a reservoir the yield of which is 40,000 acre-feet per annum, witness can see no difference in value. Of course, the reservoir would save all that part of 40,000 acre-feet that was not needed, but as compared with the direct flow, this would be of no value if it be assumed that the direct flow gave all the water that was needed.

The water in the reservoir could possibly be used to irrigate more land, but that would have to be worked out for each special reservoir.

If the water supply from a direct ditch is just as regular as the land needs, and has the same amount of water flowing in the stream every month as you would get in a reservoir, it would make no difference whether it was a reservoir supply or a direct irrigation supply, so far as that particular piece of land is concerned. It might be true that the duty of water conserved in a reservoir would be higher than the delay of direct flow water, but against this you must consider losses in delivery of reservoir water.

The local variations in precipitation, and so forth, could be counteracted by a regulation of the reservoir water, when they could not be by regulation of the direct flow, but witness thinks it
712 proper to make a comparison of reservoir and direct flow rights as shown by exhibit 40. The Brantner is as old a priority as there is on the South Platte.

Nothing is shown as to the monthly supply of the Brantner ditch. Exhibit 43 shows when the Brantner could not take water, but does not show the supply that was actually taken. If any ditch on the South Platte can get a certain and reliable direct flow supply, it is the Brantner ditch; the total volume of its decreed priority is 111 second-feet. Witness cannot tell the total amount taken by the Brantner ditch in any one month, but can tell how much it could have taken had it wanted it; the amount which they could have taken was very much more than the amount actually taken; this illustrates the frequency with which direct flow rights cannot be fully availed of. A reservoir could conserve the water and apply it later when needed. A comparison of exhibit 43 and exhibit 40 shows the difference between the Brantner's actual diversion and the amount to which it was prima facie entitled under its decree. This does not indicate to the witness that a direct flow right must have a right to take a greater quantity than it actually needs.

If a reservoir had the right to store the quantity which the Brantner ditch had the right to divert, the reservoir would have stored it and would have taken care of a much greater number of acres than the Brantner; and it is to some extent true that the Brantner must have a priority entitling it to more water than it actually uses, in acre-feet, because it has not the opportunity to store and use only when the need comes. If the Brantner right was a reservoir right, you could irrigate an enlarged acreage, but this does not illustrate the difference between whether one right would be as safe as the other one.

Does not know that the Brantner ditch has a waste-gate delivering water into Big Dry Creek. The water commissioners' reports show the actual diversion into the Brantner, and would not be cor-

rected for any thing that might be turned into Big Dry Creek; the same thing is true with regard to the Brighton ditch. Testimony as to comparison between the Burlington ditch and the Cheesman right and between the Brantner ditch and the Cheesman right, would apply to all the other comparisons made. In reality, the comparison is one between the total yields under the respective rights for the year.

The total quantity of water diverted through the Burlington, as shown by the table of water supply, might include some storage. Practically all the Burlington storage is in the wintertime; there may be some storage in 1912 that should be deducted; this would reduce duty of 4.8 acre-feet, and reduce the average duty of 2 acre-feet, and some such deduction should be made for the water that is run over the waste-gates of the various ditches mentioned.

713 Under the Fulton ditch they raise general crops—alfalfa, cereals, sugar beets, truck gardening; more truck gardening than under any other ditch considered.

Truck gardening requires more water than some other crops. [illegible]mers Independent shows an average duty of 4 acre-feet per annum; the year 1912 was a year of full flow, and the diversion in acre-feet per acre was relatively small, or about half the average, being 2.8 acre-feet.

The larger diversion in earlier years might be excessive. If that were true, the average duty would be less. In regard to Hewes & Cook ditch, in the year 1912, the duty of water was 2 acre-feet, and in 1913, a year of average flow, it was 2.7 acre-feet. The acreage is increased under the ditch.

With a total diversion not exceeding that made in the year 1909, there are about twice as many acres irrigated; the largest diversions in all the ditches seem to be in the years 1907 and 1909, which were years of full flow in the river, and it is to some extent the case that in those years water was taken because the users thought they needed it. The duty is high, and, including those duties in the general averages, raises it slightly.

Explains further exhibits 39 and 40. Referring to diagrams at the end of exhibit 40, in the right-hand upper corner, the summation of percentages is explained as follows: If there was a failure of ten per cent each year for 13 years, the total failure would be 130 per cent. The average failure should be reached by dividing the summation of percentage by the number of years included.

In comparing Cheesman with the Fulton ditch, left out of consideration entirely the performance of Lake Cheesman in 1902, which was a year of low flow. Had no data which to give the performance of the Fulton ditch that year; does not know that there would have been a very marked failure of the Fulton ditch shown in that year, but Cheesman showed good delivery. The effect of the low flow was not felt upon Cheesman until 1903, and a comparison of the performance of Cheesman in 1903 with the performance of the Fulton ditch in 1903 was, in fact, a comparison of Cheesman's year 1902 with the Fulton's year 1903. Cheesman gets the benefit of the whole diagram.

The record of the Fulton ditch for 1902 is not available.

Both the Fulton ditch and the City ditch are later than the Brantner's first appropriation. Did not know that the Brantner's ditch was forced to demand that the City ditch headgates be closed in 1902; that would indicate that at that time there was not
714 much of a supply for the Fulton ditch. Witness corrects testimony on page 2024 to read that 85 per cent is the average efficiency of delivery of Lake Cheesman.

In testifying to the possible loss in transit in the High Line canal for the East Denver Municipal District, witness was not referring to Lake Cheesman. Witness does not know whether High Line would have to be enlarged.

Lands already under the High Line could be served by supplemental supply without enlarging it. Witness' estimate of loss by seepage was based upon assumption that the High Line ditch would have to be enlarged and the "seal" broken; was not testifying as to any loss to Lake Cheesman water through carriage in the High Line.

High Line has been cleaned out so it carries about 600 second-feet, where it originally carried 550. It has been extended for a great many miles. Exhibit 43 was intended to show from the water commissioners' records the ditches in district 2 that were taking water during various weeks of each irrigation season, in order to show from the last ditch taking water what would have been the priorities under those various ditches that have been considered that could have taken water had they desired. For example, if the Brantner Third Enlargement was the last ditch taking water, then there would be certain of those priorities of various ditches that could have taken water.

On page 11 of exhibit 43 witness intended to say that during the year 1912 Cheesman Lake could have taken its full capacity; practically speaking, Cheesman could have stored all the water that entered it that year.

Witness conceives that the Cheesman decree limits to one filling of 79,064 acre-feet. Exhibit 43 is an explanation by weeks of the tables in exhibit 40, as to the conditions of irrigation in district 2. Burlington ditch omitted from exhibit 43.

Burlington ditch has the poorest direct right in district 2, and was included in exhibit 43 merely for purposes of comparison.

Explanation of exhibit 43.

Records show that the Brantner water performs a very low duty. Witness would not expect to furnish 8 acre-feet per acre out of a reservoir to irrigate land, but does not think the low duty of the Brantner water is an indication of deficiency in direct flow rights.

Redirect examination by Mr. Nye:

Water commissioners' records show the amount of water estimated by the commissioners going into the district from various sources and from seepage, and the state of the last ditch that is receiving
715 water supply, and by taking the difference between the amount going in and the amount required, they show what the deficiency would be on the commissioners' estimates.

If a flood passes Lake Cheesman at peak, it would be distributed by the time it reached district 8, or nearly; the peak would be stopped by the reservoir, and even if the spillway of the reservoir was open, the peak flood would be held up by the reservoir. It would take about 36 hours for flood to reach the dividing line between districts 8 and 2 from Cheesman, and the needs of the ditches in districts 8 and 2 are usually determinable 36 hours in advance, and it would be possible to determine whether Cheesman could store a flood by the time the flood arrived there; considered this fact in making determinations. Knowledge of these actual conditions was a factor in witness' mind.

Did not use the Denver hydrographic data in connection with the determination of storable quantities. Witness' testimony should read that up to May 1st in a certain year there was 4,000 acre-feet stored in Antero, instead of "short." Discovered the error appearing in tables in exhibit 39 for the month of May, 1910, and in the notes in exhibits 41 and 42, referring to 6,610 acre-feet, when going over the notes and recopying them; tables had then been fully prepared and printed; did not think it was of enough material difference to make a correction. The following year was a year of short supply. The amount carried forward into the year 1911 from the year 1910 was 19,412, and those figures include the error of 6,610 acre-feet. At the end of 1911 there was 3,390 acre-feet in the reservoir, and there had been stored 6,300 acre-feet. The correction of 6,610 acre-feet would make no difference, because the water was all drawn out for irrigation that year and the water remaining at the end of the year ran into the reservoir after the end of the irrigation season. If the correction for 6,610 acre-feet had been made, there would have been no different result; no part of the error would be carried forward into the 1912 tables.

Exhibit 42 shows that the High Line did not receive any water in the months of May, June, July, August and September, 1902; during October it received 160 acre-feet, during November it received a thousand acre-feet; taking into consideration the conditions of the year in respect to dryness, it is desirable to have water supply in the fall after the close of the irrigation season to be used to irrigate alfalfa and for domestic purpose, and to moisten the soil.

(Plaintiff objected to testimony regarding use of water in late fall for moistening soil. Objection overruled.)

716 It will take about 12 hours for storage at Cheesman to be felt at the head of district 8. The ditch priorities in district 2 between the Brantner Third Enlargement and the Burlington approximate 900 second-feet.

Excluding the Brantner Third Enlargement and the Burlington ditch, the priorities between the two ditches would be 600 second-feet. If the Brantner Third Enlargement was the last ditch receiving water, district 2 would be short 557 second-feet of supplying the ditch priorities prior to Cheesman. The ditches between the Brantner Third Enlargement and the Burlington are the Lower Latham, Union, Side Hill and Fulton, having a total decreed priority of

557.33 second-feet. Including the Burlington it would be 907 second-feet, so that when the Brantner Third Enlargement is the last ditch drawing water in district 2, there are 907 second-feet of unsupplied priorities antedating Cheesman, and there is also the unsupplied priority to the City ditch for 42.95 second-feet.

When the Brantner Second Enlargement or the Fulton First Enlargement are the last ditches drawing water, there are unsupplied priorities of something over 900 second-feet. In considering the commissioners' reports, took into consideration the general conditions existing at the time, as shown by reports previous and subsequent.

In determining whether high flood could be stored, witness took into consideration practical operation, and did not cut out each flood with reference to the conditions existing at the time it occurred and permit it to be stored in Cheesman, nor did he cut down Cheesman supply when the river would drop very low for a day or two; referring to the month of October, 1911, in that month witness thinks there are other rights between the High Line priority and the Antero storage right which would have had the right to store if Antero's storage was lawful; and the fact that the High Line itself was not demanding water in that month, would not legalize Antero storage.

The precipitation in September, 1911, was 78 per cent of the normal, and in October of that year was 35 per cent of normal, and in August of that year was 79 per cent of normal.

The report by the water commissioner of the water coming into the district includes the seepage

Describes again operation of reservoir on 60,000 acre-foot draft. You might sell on a basis of 60,000 acre-feet or on a 50,000 acre-foot basis. The man who bought a share on a 60,000 acre-foot basis would get less water per share and pay less for it. Barr Lake Enlargement had not been increased in 1910; it was completed in 1911.

Mr. Taylor was appointed receiver for the Denver Reservoir Irrigation Company on the 1st or second of June, 1910. Re-
717 ferring to cross-examination on month of June, 1910, the storage being diverted at that time must have been on the Burlington priority for old Barr Lake, or the Oasis reservoir. Witness estimated loss by seepage in Barr Lake of 6,000 acre-feet annually; made no investigation as to evaporation.

Estimate of seepage was made in April, 1908, for The Denver Reservoir Irrigation Company; actually measured the seepage.

Exhibit 40, showing comparison of direct flow water supply with Cheesman supply, was made to show a comparison of the efficiency of supplies; and if equal supply is shown, flexibility is immaterial.

If witness applied his assumed draft on Lake Cheesman to the additional months of April, May and October, it would have affected the delivery of water in the years 1902 and 1903, increasing it slightly; it would have made no difference in the years after 1911.

On rearranging distribution, would take 25 per cent off of the month of April, May and October, and add it to the months of June, July and August, distributing about 20 per cent of that in April and May, and 5 per cent in October. Has not undertaken to arrange percentages for the months of April to October, inclusive, but that would

have saved water that went over the spillway in April and May of one year. In Exhibit 40, the summation of departure of percentages is 156, and that is in relation to 1100 per cent.

The Brantner ditch departure has been 87 per cent.

A short year affects the direct flow right in that year, and might affect a storage right in that year or a subsequent year. The Fulton ditch headgate is below the sewage discharge from the city of Denver.

Several ditches between the Fulton and the sewage; has not assumed in any of his tables that it would require a 8 acre-feet per acre out of a storage supply.

In 1910 some water was run on the enlarged Burlington storage right; enlargement was not completed.

Recross-examination by Mr. Dorsey:

Water diverted for storage into the Burlington ditch in 1910 might have been on the later Barr Lake priorities, subsequent in time to Cheesman; only used the hydrograph in exhibit 37 to show floods at Platte Canon.

Peak floods could not be stored if, looking into the future, they would be needed in the district below by the time they could reach there. The reservoir will catch the peaks of the flood, but if it turned out that the water was then needed below, it would have to be
718 turned out; but it would not have to be turned out if the need had ceased to exist at the time the water could be turned out and reach the ditches.

Does not know of any reservoirs in this vicinity operated in that way.

Witness always noted the actual storage at Cheesman, but did not always include it; commissioners' semi-weekly reports only exist for the years 1911, 1912 and 1913, and for district 2. None exist for district 8; might not have given any effect to these semi-weekly reports, but read them, and about the only consideration given them was to determine when certain ditches were not receiving water. Witness did not know that litigation over fall ground storage was pending until it was mentioned by counsel.

Witness thinks storage could not have been permitted in October, 1902, because water was needed to soak up the ground. Recalls that the September rainfall was 370 per cent of normal for the month, and that was followed by snow in October.

Must use judgment in considering data.

Did not know or take into consideration the fact, if it be a fact, that water cannot be taken for direct irrigation after the first of November. Witness meant to give the figure 907.33 second-feet as the decreed appropriations intervening between the Brantner Third Enlargement and the Burlington.

Did not mean to say that the ditches having these decrees had a capacity to take that much water. In the case of the Fulton ditch, the decree priority is 448.8 cubic feet, and the capacity is 300 statute feet.

The Lower Latham ditch has a capacity of 200 second-feet, and a decree of 287 second-feet; the Union ditch has a capacity of 100

second-feet, and decree of 184 second-feet. There possibly is no Side Hill ditch. In denying Cheesman storage for October, 1911, considered the dearth of rain in August and September of that year, and denied Cheesman storage in October, 1902, although the rainfall for September was 370 per cent of normal, but does not consider the general conditions the same.

The fact that in October, 1911, Antero reservoir was storing and Cheesman was storing, and the intervening direct rights were not drawing water, would indicate that there was not a need of water for direct irrigation during that period, and the fact that there was snow and cold weather during that month would be an additional element; in computing seepage from Barr Lake figured the whole thing upon measurement of the evaporation in April, 1908; measured the current flow at several points below the reservoir. Barr Lake is on an arroya; seepage from the dam is caught in a series of seepage ditches carried into the arroya.

719 The betterment work on Barr Lake was begun in 1909; some work was done in 1909 to correct Barr Lake seepage.

Does not think the decree for enlarged Barr Lake is like the one for the original. Adding more water to Barr Lake and thereby increasing the seepage, would not increase the amount of water that could be taken under the decree. These seepage measurements made in April, 1908, covered two or three days; cannot give the exact date; cannot give the detail now.

The total amount received for Cheesman water ought to be the same whether operated on a 50,000 or 60,000 acre-foot draft.

A. Lincoln Fellows.

Direct examination:

A. Lincoln Fellows. Member of the Public Utilities Commission of Denver, one of the defendants in this case; have been such member for four years and five months. Civil engineer for 27 years. Graduate of Yale College. Practiced profession for the most part in Colorado, but also in the West generally. Practice confined almost altogether to irrigation engineering.

First connected with Montezuma Valley irrigation project, in Southwestern Colorado, for about eight years. After that deputy state engineer. Since then connected with a number of irrigation projects, generally in a consulting capacity; except while district engineer of United States reclamation service, at which time particularly connected with Uncompahgre project and Grand Valley project. During more recent years member of firm, afterwards of company, Field, Fellows and Hinderlider. Also member of Public Utilities Commission.

During my practice have been occupied in a consulting capacity in connection with irrigation projects, among which are: French Land & Irrigation Company, New Mexico; Sheridan Irrigation District, Wyoming; proposed extension Twin Falls project, Idaho; matters in connection with proposed Willow Creek project, Oregon; Two Buttes irrigation project, Southern Colorado; proposed Prowers irri-

gation project, in Colorado; North Fort Morgan irrigation project, in Colorado.

Have given a good deal of study to water supply in South Platte river, commencing about the year 1897, when I was deputy state engineer. Established a number of gauging stations. About 1901 published a pamphlet entitled "Water Resources of Colorado," tabulating information I then had as to water supply of the South Platte. Since that time have made examinations and studies as to flood waters of the South Platte.

720 Have been present during practically all of the hearings in this case, and have heard the testimony of witnesses concerning water rights. Have seen and examined the various exhibits.

Exhibit 44 was prepared as the result of my studies, and relates to Lake Cheesman and other water rights claimed by the company. The studies upon which this exhibit was based were made entirely during the prosecution of this case.

I have listened to the testimony in connection with the water supply available for storage, and have examined the various exhibits relating to that subject. I have also made an entirely independent examination and study in respect to possible storage at South Platte and, carrying that examination one step farther, as to available storage at Lake Cheesman.

General method has been as follows: Year 1913 considered a fair normal year. Have taken use of water for irrigation purposes in Districts 8 and 2 made that year as approximately the amount of water to be demanded for irrigation purposes on the average in the coming years. 1913, practically to all intents and purposes, a year of normal precipitation. Precipitation records appear in Exhibit 44, page 1, table 1.

1913 was a good year as to flow, as shown by Exhibit 44, page 3, table 4. This table prepared from all available information as to the flow of the South Platte river at South Platte. Comstock's table of flow, corrected for Lake Cheesman storage, used where available. Some years estimated to some extent. Purpose of table to show general character of years, from which it appears that the discharge in 1913 was 113 per cent of normal. Back of 1899 the data was so incomplete that percentages were not figured. An additional reason for using the year 1913 was that it was the last year with complete records, and that the records furnished by the commissioners of the various districts and the division engineer for that year were the best that I was able to examine of those on file in the State Engineer's office. Therefore I assumed that the use of water from the river for irrigation purposes in 1913 might fairly be assumed to be the average use of water during the coming years.

Next I took the actual discharge of the South Platte river at South Platte, as nearly as I could arrive at it, during the 14 years from 1900 to 1913, inclusive; also the discharge of the south fork of the South Platte at Lake Cheesman; I considered those as being the probable discharges of the river at those points in any future period of fourteen years.

To those stream flows I applied the demand upon the river as shown by the uses of water in 1913, and so arrived at what I

thought to be a fair conclusion as to what water might be stored in Lake Cheesman.

721 Method further explained.

On the whole, I concluded that 1913 was the best year I could find for this determination, and so used it.

Exhibit 44, page 2, table 2, states yearly flow and monthly averages of south fork at Cheesman, taken from reports furnished by the Water Company. Same page, table 3, shows relation of flow on south fork to flow for same months and years at the forks. By it the average yearly flow at Cheesman appears to be 44% of the total flow in the stream at South Platte. Have used these percentages to fill in the incomplete months on table 4, page 3, Exhibit 44, indicated by stars. Knowing flow at Cheesman but not at South Platte, the latter discharge has been filled in by proportion.

Exhibit 44, page 4, table 5—discharge of south fork at Cheesman, taken from records of the Water Company on file in State Engineer's office.

Exhibit 44, page 5, table 6, from water commissioners' reports. I assumed that entire inflow from St. Vrain and Big Thompson was required to be sent down to District No. 1; but the seepage in entire District 2 assumed as available for irrigation purposes to the ditches within the district.

Exhibit 44, page 6, table 7—inflow from side streams and seepage in Water District No. 8; amounts shown being those reported by the water commissioner, except those indicated by a star, which are estimated.

Exhibit 44, page 7, table 8; similar information for District No. 2, covering inflow from Clear Creek and seepage, as reported by the commissioner in general way throughout the entire year. In this table seepage includes inflow from Denver sewers.

Exhibit 44, pages 1, 1*a* and 1*b*, dealing with precipitation at Denver and Lake Cheesman.

Exhibit 44, page 8, table 9; diversions for irrigation in District No. 8, as reported by water commissioner, also the quantities decreed to the respective ditches prior to the first decree of Lake Cheesman.

Exhibit 44, page 8, table 10, shows totals for District No. 8 for same year and same ditches, as reported by the water commissioner.

Exhibit 44, page 9, table 11; same information for District No. 2, as reported by the water commissioner; this table corresponding to table No. 9.

Exhibit 44, page 10, table 12, presents same information, derived from water commissioner's report, in respect to District No. 2 as does table 10 in respect to District No. 8. On this table question marks appear where the water commissioner has reported the acres

722 actually irrigated to be in excess of the acres irrigable.

Exhibit 44, page 11, table 13—diversions of the Water Company near Platte Canon, as reported by the Water Company. Figures obtained by me from the company, for the most part, at the time the valuation was being made by the utilities engineers. Those for November and December have been obtained since.

Exhibit 44, page 12, table 14; compilation of data shown in preceding tables. Said table further explained. For the months of Janu-

ary, February, March, April, November and December the diversions of the Water Company are set down as demands on the canon, because the intakes of the Water Company are so high up on the stream that the inflow from seepage and small streams cannot be utilized for these particular diversions. For the remaining six months the deficiency of the inflow from seepage and tributaries below the irrigation diversions is added to the amount diverted by the Water Company, as giving the total demand upon the canon.

Exhibit 44, page 13, table 15, shows available storages at Lake Cheesman, applying the demands upon the canon, so determined, to the stream flow, for the year 1900 to 1913, inclusive. In making this determination demand at the canon for each month is deducted from flow of the South Platte at the canon, and the excess, if any, permitted to be stored at Lake Cheesman, to the extent of the flow in the south fork at Cheesman, as shown by the column relating to the discharge of the south fork at Cheesman. If the demand at the canon equaled or was greater than the discharge at the canon for that particular month, no storage was permitted.

Exhibit 44, page 13, table 15, further explained.

Exhibit 44, page 20, table 16, is merely a summation and an average of the conclusions of the preceding table relative to the available storage in each year, limited, however, by the total quantity allowed to be stored in each year by the present decree, to-wit, 79,064 acre feet.

Exhibit 44, page 21, table 17—evaporation and other losses at Lake Cheesman, explained.

The vertical loss in each month determined by taking the amounts given in Wilson's Irrigation Engineering for the evaporation at Cheyenne, Colorado Springs, Denver and Pike's Peak, and taking the average of these for the evaporation at Lake Cheesman. Evaporation at Cheyenne, Colorado Springs and Denver would probably be somewhat too high, so the Pike's Peak record was taken into the average, upon the assumption that this would balance the excess. The average for the four stations mentioned is 57.9 inches in the year,
723 and I have increased the amount to 61.25 inches to include other losses, such as water used for generating plant, certain seepages through the gates, and a little loss through the cracks in the hill.

Exhibit 44, pages 22-28—tabulation of operating results during the fourteen year period, on an assumption of an annual draft of 40,000 acre feet, and upon the estimated possible storages shown in the preceding tables. Evaporation for each month determined according to factors shown in table 17, page 21, Exhibit 44, applied to an exposed surface estimated by taking the amount in the reservoir at the first of the month, the amount in the reservoir at the end of the month, and averaging them, thus finding approximately the average area for the month. The amount of evaporation deducted each month, except in those months when the reservoir was full and additional water was available under the appropriation, when the amount of evaporation was not deducted from the amount in the reservoir, but the reservoir was allowed to fill and the evaporation charged up against the appropriation as a storage.

Said tables further explained.

I have not yet reached a definite conclusion as to the proper draft under which to operate Lake Cheesman to show the highest efficiency and utilization of this supply.

Exhibit 44, page 3, table 4: the figures given for individual months of the years 1887 to 1899 enter into the averages for the respective months at the foot of the columns, therefore they enter into the determination of the monthly and yearly mean, with which the years 1900 to 1913 have been compared to ascertain the yearly percentage.

The Cache la Poudre enters the Platte at the lower end of District No. 2, and its discharge is available in District No. 1, but not in District No. 2. The amount discharged from the Poudre is not reported upon by the water commissioner of District No. 2.

The method I employed to estimate possible storages at Lake Cheesman was as follows: I ascertained the discharges for the series of fourteen years immediately preceding the year 1914; I also ascertained the amount of water used, as reported from various sources, in the year 1913; from those reports I ascertained the demand on the canon for the year 1913. I assumed that the year 1913 represented fairly the demand which might be expected on the average in the future; accordingly I used the demand which I had ascertained as a constant which I applied to the quantities which had been discharged in each of the series of fourteen years which I have just mentioned, arriving in that way at what might be called the expected available storage for any subsequent period of fourteen years.

724 Exhibit 44, page 22, year 1900: I assumed that the reservoir would at the beginning of the year be filled to one-half its capacity. That is because the year 1899 was known to have been a year of good supply and the reservoir could probably have filled. At any rate there would probably not have been any shortage at the end of the year. The assumption was made that the reservoir was half full as a rather more reasonable assumption than either that it was full or that it was empty.

There is a considerable variation in supply in different years, some years being very deficient in supply and other years having a surplus over the average.

Referring to table 4, page 3, Exhibit 44: I had not before noticed that the year 1908 as there given appears to be the lowest in percentage. I had thought that 1902 was shown as the lowest. But these tables serve to show the wide variations in the discharge of the stream in different years. The demand, however, is assumed to be fairly constant quantity.

This period of fourteen years is used as the period of supply because it is the longest period that we have with anything like satisfactory records as to the flow in the streams. It is practically impossible from the records to get anything like a satisfactory average as to the demand on the water in the streams, for the reason that the commissioners' reports are very incomplete up to within the last two or three years; in the year 1912 the conditions were abnormal—exceedingly so; in the year 1914 they were abnormal; in the year 1908 it was the opposite way; in the year 1911 there were features

that were hard to be considered or to adjust; "and consequently the year 1913 was assumed as the best information that could be obtained as to the average demand upon the stream."

As to stream flow, it was considered that fourteen years should be sufficiently long to give a fairly accurate idea as to what might be expected; it should furnish a fair average, and should give fairly representative information as to what might be expected for any similar period in the future. This series of years covers years of deficiency and years of full supply, and years of practically every type that need be considered in a computation of this kind.

Exhibit 44, pages 29-35: tables showing operation of Cheesman on 50,000 acre foot annual draft, according to assumptions and estimates of Fellows. These tables explained.

In the tables relating to the 40,000 and 50,000 acre foot draft the calendar years are not given, but the years of the fourteen year period are numbered; the calendar year in each instance can be obtained by subtracting 1 from the number of the year given in the table, the series in each instance starting with 1900.

725 In the tables relating to the 40,000 and 50,000 acre foot draft respectively, the assumptions are the same as to possible storage, as to percentages of withdrawal in each month, and as to the factors of evaporation.

Exhibit 44, page 39 is a diagram showing water surface area in relation to the contents of Cheesman. This was used in determining amount of evaporation.

Exhibit 44, page 37, shows data upon which my estimates as to the factor of evaporation and other losses in each month was based. This factor was applied to the average area in each month, obtained by taking the mean of the contents at the beginning and at the end of the month.

Exhibit 44, page 21, table 17, is a tabulation of these monthly factors.

Exhibit 44, page 36, is a table of comparative efficiencies under the assumed draft of 40,000 acre feet and 50,000 acre feet per annum, respectively. Exhibit 44, page 40, is a diagram showing the same thing. Undoubtedly the use of the water would not be exactly as it is represented in this diagram by the seasonal demand. The owners of stock in the reservoir would undoubtedly be more careful, and would not use the water on the basis shown on this diagram. I have placed the curves of seasonal demand on this diagram in the same way for each year, because it would be impossible to determine just what basis the irigators would use in distributing the amounts of water in the reservoir in those years when there was not sufficient water to supply the total demand. My conclusion is that the 40,000 acre foot basis of delivery is the one that should be considered, as offering what might be called a fairly guaranteed supply of water.

According to my estimates and assumptions, the reservoir would show an annual draft of 35,000 acre feet, 100% efficiency; 40,000 acre feet, 95.6% efficiency; 50,000 acre feet, 91% efficiency. I concluded that it would probably not make very much difference to the seller whether he sold on the basis of 40,000 acre feet delivery

with 95.6% efficiency, or on the basis of 50,000 acre feet delivery, with 91% efficiency. I assumed that the seller would prefer to be more nearly on the safe side, and would make the sale on the lesser draft, if the amount to be received were not material. A number of things would have to be considered. The market would have to be obtained. On the greater draft sales would have to be made amongst a greater number of people, probably, and upon a little different basis—that is, a basis of less efficiency; and the seller would be unable to say that the amount to be delivered was every year the amount contracted for. Taking these things into consideration, and also the probably greater length of time required to sell the water on
726 the larger draft, and the consequent greater overhead charges and possible discount, I concluded that the amount which would be received on the 50,000 acre foot basis would probably not be more in the aggregate than upon the 40,000 acre foot basis; that the return to the seller would be the same in either event.

Exhibit 44, page 38, shows my conclusions as to the water rights of the company, including my valuation upon each. As to Marston Lake, have assumed that actual diversions of the Water Company near Platte Canon, as shown in Exhibit 44, page 11, table 13, for the months of January, February, March, April, November and December could be stored therein, taking only as much of the April diversion as was necessary to fill Lake Marston to its capacity.

Rough and Ready Mill Ditch, merely assumed to make more safe and available the Platte Canon ditch rights. No separate value assigned.

I arrived at that conclusion as to the value of these water rights. Have in the past been in touch with the value of water rights, and made many estimates as to the value of irrigation supplies. Have made a study of the combined value of land and water, when used for the growing of crops, along the valley of the Platte. Have had personal experience in relation to water values in various systems along the Platte, and have examined into the question. These investigations have in this locality covered practically all of the past fifteen years.

(Witness' statements as to value of water rights objected to, because he has not been shown to be competent to express such an opinion. Objection overruled. Exception.)

My conclusion as to values is set forth in Exhibit 44, page 38.

As to Lake Marston, considered that probably about 2 acre-feet per acre per annum, measured at the reservoir, would be required by the irrigators, the purchaser standing the loss in transit between the reservoir and the land.

Exhibit 44, page 38, group "A": the item following Marston Lake reservoir relates to summer flow from Water Company's sources of supply near Platte Canon, based on actual diversions made in May, 1913, as shown in Exhibit 44, page 11, table 13, from which deduction is made for the Lehow right (3.14 second feet) and for Hugens and Shellabarger (3 second feet), leaving 80.16 second feet as the total amount of water available for sale as direct flow rights during the irrigation season. I valued this upon the direct flow basis, as-

suming that the water would in the main have to be transferred to other ditches; that they would have to go through the process of having the point of diversion changed; that that portion of
727 the 80.16 second feet not now decreed would have to obtain decrees; that they would have to go through all of the legal routine necessary to make that water available for transfer and suffer possibly certain discounts because of the estimated loss in seepage etc.; that purchasers would have to be found for the water; that all that the Water Company would have to sell would be a certain claim for water, at the points where it is now diverted; that the ditches for conveying the water to other lands would have to be found or constructed, and difficulties of that kind eliminated. By considering all of these details I arrived at my conclusion as to what the water was in my opinion worth, to-wit, $2,000 per second foot, giving a total for the 80.16 second feet of $160,320, for irrigation purposes. Adding this to the value already estimated for Marston Lake makes a total for group A, page 38 of Exhibit 44, of $754,170.

Exhibit 44, page 38, group "B"—Bear Creek and Turkey Creek rights: have assumed that water yielded by these rights could be utilized in existing reservoirs belonging to the Water Company, to-wit, Harriman reservoir, Soda Lakes reservoir, the Bergan reservoir. Have therefore assigned values as storage water. I applied a value of $35 per acre foot to a yield of 6,840 acre feet; assigned a higher value per acre feet here than to the water in Marston Lake, because in my opinion Bear Creek and Turkey Creek rights are in a somewhat better position from a legal standpoint than the storage rights upon the South Platte. They are already decreed for storage, while the South Platte rights are not. Also considered fact that lands to be irrigated are nearer these sources of supply. All of these estimates are based upon irrigation use, and an assumed transfer from domestic supply to irrigation use. As to group B, it was my opinion that water could be utilized practically upon basis of about 1¾ acre feet per acre per annum, there being less loss in transit than would be the case with South Platte water. The values were assigned upon the quantity measured at the outlet of the reservoir.

Exhibit 44, page 38, items 5 and 6—old Denver City right and Mississippi Street galleries, considered together: assumed old right merged with Mississippi Street galleries claim; as to quantity, took rate at which water pumped in 1910, to-wit, 21.2 second feet, that being the maximum monthly average in that year; considered this as a right without a decree, simply a claim; subject to the various discounts spoken of above, connected with transfer and changing point of diversion, and losses and expense connected therewith, and especially the fact that water is derived from infiltration galleries; such galleries of perishable nature. What the Water Company could sell and transfer would be simply the right to produce water by means of the infiltration galleries. The water was practically of no value, so far as transfer for irrigation purposes was
728 concerned, therefore gave it nominal value of $100 per second foot; meaning by that, over and above overhead charges

necessary while finding market and disposing of it to possible purchasers.

Exhibit 44, page 38, item 7—Cherry Creek right; considered in the same way. Assumed possible diversion of 8 second feet and applied nominal value of $100 per second foot.

Exhibit 44, page 38, item 11—Highline ditch right: Present market value applied; differs from items 5, 6 and 7 in that ditch exists for diversion, and a proportionate interest in it passes with the right.

Exhibit 44, page 38, item 12—Lake Cheesman: to the 40,000 acre foot draft, assumed by me as being the most practical draft for sale and delivery for irrigation purposes, have assigned a value of $35 per acre foot; this upon assumption that 2 acre feet per acre per annum, delivered from outlet of reservoir, would be required for the irrigation of any lands likely to purchase that water, under any of the existing ditches near or below Denver; assumed the most likely possibility for the use of that water would be in connection with the Highline ditch; assumed delivery at the outlet of the reservoir, purchaser to stand losses of evaporation, seepage, etc., between that point and his land; and assumed that the gross cost of the structures required to make the various supplies available should be deducted from the gross value for irrigation, to arrive at the net value for irrigation. The gross values which I have assigned in Exhibit 44, page 38, include cost of structures. The value to be deducted from this on account of structures should be, in my opinion, the gross value, without deduction therefrom on account of depreciation. It seems to me that the structures necessary to produce the water should be required to be in perfect condition, or practically in a new condition. I have limited my valuations to what I thought the farmer in this locality could afford to pay.

(Exhibit 44 offered and admitted.)

Cross-examination:

In estimating demand on canon, which must be satisfied before Cheesman can store, I considered the demands for Districts 8 and 2 specifically. As to districts below 2 I assumed that a certain amount of water was necessary to pass from District 2 to District No. 1 to supply priorities below. I assumed that those priorities in District No. 1 earlier than Cheesman would be satisfied by the inflow from the St. Vrain, the Big Thompson and the Cache la Poudre. I assumed that the inflow from those streams would in general
729 supply the demands of ditches lower down. I considered that a fair and reasonable assumption.

For District No. 2 I used as a basis the diversions of the ditches earlier than Lake Cheesman, except the Lupton Short Line, which has a decree later than Cheesman's first decree, but prior to Cheesman's last decree. Cheesman's first decreed priority is for a little over 30,000 acre feet; its last decreed priority for 48,373 acre feet, and the Lupton Short Line intervenes.

As to the other ditches in Districts 8 and 2, the demands as esti-

mated by me were the amounts as reported by the commissioners as used for irrigation during the year 1913, without passing upon the question as to whether it was properly or economically used or not.

Generally speaking, the need of these ditches is the amount of water that can be and is beneficially used, within the limits of the decrees of the respective ditches utilizing the water. Limited by the quantities specified in their respective decrees, I would say that such ditches are entitled to divert at all times what the commissioners of the respective districts said that they were enitled to divert. Unless there was a surplus of water in the stream the commissioner would not allow them to take more water than their decrees called for, and he might very properly limit them to amounts considerably less than their decrees. If the water is being wasted, I think the amount should be decreased at the headgate. Allowing water to run in at the headgate and out at the other end of the ditch might possibly be a waste if it could not be used by other ditches below, but if nobody was injured by carrying water through the ditch, and it was returned to the stream, it would not be a waste. Where such a process as that is indulged in by ditches, the quantity of water thus taken in at the headgate and later allowed to flow back into the stream should be counted and included in the diversion reported by the water commissioner. Sometimes more water than is actually used for irrigation must be run through a ditch to keep up a proper head to supply those at the lower end, but if that is done to excess it is a waste.

The water commissioner has not the authority, and ordinarily has not the data, to determine whether a wasteful use of water is being made by the ditches. I think other users of water are justly entitled to relief against a ditch or ditches which are diverting water and spreading it upon their acres in quantities in excess of that which is really needed for the purpose of raising their crops.

In this case I have taken as the absolute measure of the needs of the ditches the diversions made by them in the year 1913, as reported by the water commissioners of Districts 8 and 2. I
730 have used those figures as the measure of what those ditches will be entitled to divert in the future, as against any claims for storage at Lake Cheesman.

Having so determined the total demand, I ascertained the proportion thereof which must be satisfied by water flowing at Platte Canon as follows: (1) I ascertained the total quantity of inflow into District 8 from sources other than Platte Canon, that is, from seepage and from the various tributaries entering the district; (2) I ascertained the total quantity of inflow into District No. 2 from sources other than water flowing past Platte Canon, that is, from seepage, from the sewers of Denver and from the various tributaries; (3) from the quantity of inflow so determined for District No. 2 I deducted the inflow from the St. Vrain, the Cache de Poudre and the Big Thompson, because I considered that needed for District No. 1; (4) all of the balance remaining of inflow and accretions from tributaries and seepage in Districts 8 and 2 I deducted from the total needs of the ditches determined as above; (5) the balance

remaining after making that deduction was assumed by me to be the demand of those ditches in Districts 8 and 2 upon the stream flow at Platte Canon, which must be satisfied before Lake Cheesman can store. I made this determination for each of the months April to October, inclusive.

Having so ascertained the demand for each month upon the canon, expressed in a total quantity of acre feet, I then examined the monthly discharge at the canon for each of those months, and if the discharge for a particular month was in total quantity less than the total quantity of the demand for said month, thus arrived at, I determined that for that par-icular mon-h there could be no storage at Lake Cheesman. But if there was an excess of discharge in acre feet over the demand in acre feet for that month, I estimated that Cheesman could store said excess, to the extent that it was flowing in the south fork of the South Platte at Cheesman.

In determining the demands I added to the irrigation demands the Water Company's diversions below the canon.

The determination of the needs of these ditches is based entirely upon the reports of the water commissioners as to the actual diversions made in the year 1913. The deductions which I made from the total gross amount of those needs, on account of inflow from tributaries and seepage, are based absolutely upon an adoption of the figures for such inflow and seepage as reported by the water commissioners for the year 1913.

The real needs of a ditch for direct irrigation are dependent upon many different conditions and considerations, such as precipitation, temperature, etc., which have an effect upon the quantity of
731 water really required. Therefore the real needs of particular ditches for the irrigation of identical acres vary from year to year.

The flow in the various streams, both in the South Platte itself and in its various tributaries, is subject to great variation from one season to another. The flow varies greatly from year to year, even from month to month, and sometimes from day to day. That is characteristic not only of the South Platte, but also of the various tributaries which enter it in Districts 8 and 2. The quantity of water discharged into Districts 8 and 2 by these various tributaries has a material effect upon my determination of the demands of these ditches upon Platte Canon. These tributaries come from different drainage areas, having their heads at different places along the mountain range, and are subject to different conditions, as to snowfall in winter and rainfall in summer; as to weather, temperature and other conditions at the headwaters of the various streams, which affect their flow. Nevertheless I have taken and used as a constant quantity the inflow of these tributaries as reported by the water commissioners for the year 1913. The water commissioners of Districts 8 and 2 did not measure the inflow of these various tributaries; they merely estimated them. There are no gauging stations. The water commissioner merely estimates and reports in his weekly report the rate of flow of these various tributary streams on the date of his report. Using the rate of flow so reported as a factor, and assuming that the water flowed at that rate during the preceding

week, I have by computation determined what would be the total discharge of the tributaries in acre feet.

As to seepage also, the quantities reported by the water commissioners are mere estimates, not dependent upon any measurement at all. The water commissioners usually estimate seepage as follows: First, they take the sum of their estimates of the inflow into the district in the main stream and of the accretions in the district from tributary streams; second, they take the sum of their estimates of outflow from the district in the main stream and of diversions by the ditches in the district; third, they deduct the total inflow, so determined, from the total outgo, so determined, and the remainder they call seepage. In the water commissioners' reports the quantity of seepage is expressed in second feet. For the purpose of my computations here I have converted it into acre feet. The water commissioner in estimating seepage is, I think, guided to some extent in his judgment by what does actually return to the river between certain heads of ditches, but I do not know that any such condition occurred in 1913 as would enable him to get that information.

732 The State Engineer made no seepage measurements until late in the year 1913. Prior to that time none had been made for a number of years. The statements of the water commissioners in their reports for 1913 concerning the rate at which water is returned into the main stream by way of seepage are estimates only, and not based on measurements, or on any very complete data. The water commissioner's reports as to inflow to and outflow from his district in the main stream are probably estimates, although the water commissioners of Districts 8 and 2 ought to have had some knowledge of gaugings at Platte Canon and Denver.

There is no gauge station at the lower end of District 2. Even where gauge stations exist, I do not think the water commissioners go to read the guages, or report the inflow and outflow by such readings. The water commissioners estimate the stream flow, even in the main stream, and with great frequency their estimates are far from being correct.

Their visits to the tributaries for the purpose of making an estimate of the flow therein are, I think, likely to be rather infrequent. There are many diversions for irrigation purposes from the tributary streams before they reach the main stream in Districts 2 and 8. The inflow into the main stream from these various tributaries is very materially affected by such diversions, and those diversions, in turn, are influenced from time to time and from year to year by the circumstances and conditions surrounding agricultural operations and irrigation processes. The quantity diverted from these tributaries is not a constant quantity from year to year, and that circumstance certainly affects the quantity of water which remains in the various tributary streams and flows into the main river.

The amount of accretion to the stream from the sewers of Denver is estimated by the water commissioner of District No. 2. It is not a constant quantity, but varies materially at different seasons and under different conditions.

I have expressed my demand upon the canon in terms of acre

feet for the month. Unless in the course of a particular month the aggregate flow at Platte Canon has been such as to furnish that certain number of acre feet in total quantity expressing my estimated demand for the month, then, according to my method, there could have been no storage at Lake Cheesman during that month. But if the discharge at Platte Canon for the month, expressed in acre feet, has exceeded the number of acre feet estimated by me as the total demand on the canon for the month, then I have permitted that excess to be stored at Lake Cheesman in that month, to the extent that it was flowing in the south fork of the South Platte at Lake Cheesman.

733 This method prevents Cheesman from storing during periods of flood unless the total discharge for the month, expressed in acre feet, exceeded the total of the demand for the month, likewise expressed in acre feet, no matter what might have been the rate of flow in the river at the time the flood was occurring. Nevertheless I adopted this method, because I thought there were balancing features on the other side.

Storage reservoirs really do get a substantial part of their supply from the summer floods. It is in the main true that direct supply ditches are not entitled to take water and cannot use it beneficially at any greater than a certain rate, no matter what may be the rate of flow in the stream. They are in the first place limited by the rates of flow specified in their decrees; secondly, they are limited by the capacity of the ditches to convey; and in the third place, even though the decree of the ditch specified a greater rate, and even though the capacity of the ditch permitted a diversion of a greater rate, nevertheless, the ditch would be limited to a diversion of only such quantity as could be beneficially applied, no matter how great the flow might be passing down the river. Those are proper limitations, and a ditch would be subject to them even at times of flood, and even though previously it had not been receiving its full quota because of low water in the stream. If in a month of thirty days, the river had been low for the first twenty-five, and there came a good sized flood in the last five, but the total discharge in acre feet for the month had been less than the total quantity in acre feet of my estimated demand for that month, I do not say that because of the shortage earlier in the month the ditches would be entitled to make up out of that flood the deficit from which they had previously suffered, so that they might obtain as nearly as possible their full quota of acre feet for the month.

I think it is true that the water commissioner in each district always looks at the ditches in his district with rather an eye of generosity. He is going to be liberal with those ditches. He is a kind of a local advocate of his particular ditches, as against diversions in other districts.

Storage at Cheesman might occur on the peaks of floods even in a month when the total discharge, expressed in acre feet, was less than the total quantity of demand of ditches as estimated by me. It is highly probable that such floods will occur. They occur with some frequency. We must bear in mind that a flood at Cheesman, or high up on any of the tributary streams, will be flattened out to a

very great extent before it has supplied the needs of the ditches below.

If there were floods in the early part of a certain month and low water later, so that for the entire month the total discharge,
734 expressed in acre feet, is less than my total estimated demand for said month, likewise expressed in acre feet, nevertheless, if the rate of flow during the days when the flood continued was such that, in addition to supplying the needs of the ditches, there was an excess which Cheesman could and did store, such storage would be proper. It is not only possible, but probable, that such a condition might arise. But under my method of determination, possible storages of that sort are eliminated. I have offset against possible storages: (1) the flattening out of the river before reaching the ditches, as mentioned above; (2) an assumption that the recorded stream flows at Platte Canon are somewhat—I do not know how much; a few percent—in excess of the actual supply.

These are the figures reported by the hydrographers and used by me, but it is my experience that those who measure water generally get a larger quantity at a station where the stream bed is rocky or filled with boulders than they do where the stream bed is smooth. I say this, although these figures are the result of actual measurements made by gauges and by trained engineers and hydrographers experienced in such matters. Although I regard these measurements of the stream flow, made by trained and educated hydrographers, and based upon their own readings of the gauges and other measuring devices, as inaccurate, and therefore to be decreased by a certain percentage, nevertheless I accepted the statements of the water commissioners concerning stream flow, which are mere estimates, at their face value, for the reason that the reports from the water commissioners are all the information we have regarding that particular point, and I assume that their errors will offset one another.

A great many of the recorded measurements of the stream flows at these stations have been made by United States hydrographers, others by those of the state. I think they are generally accepted as the best and most accurate information obtainable. I base my conclusion that these measurements are uniformly high upon my own observation regarding measurements in rocky channels; that they are almost invariably a little high. I think, on the average, they should be discounted about five per cent. But that would depend upon whether the hydrographer himself had applied any factor of correction. As to these particular measurements, I do not know that no factor of correction was applied, except as to measurements which I myself made for two or three years in the period between 1898 and 1905. I did not apply a factor of correction.

Prior to 1900 the measurements were made at Deansbury; afterwards at South Platte. The stream bed at South Platte is
735 rather a gravel and boulder bed than what is generally regarded as rocky. As to the measurements at South Platte, the necessary deduction, assuming that no factor of correction had been applied, might possibly be as great as five per cent. I have made no specific deduction.

If it should turn out that the actual diversions of the ditches in 1913 did not represent their actual needs for the beneficial and proper irrigation of the acres under them; or if it should turn out that the water commissioners' statements as to the quantity of those diversions for that year were erroneous; or if the water commissioner was mistaken in his estimate of the quantity of inflow into his district from tributaries, from seepage and from sewage; the result of a mistake in any of these matters, as I have already testified, would have a material effect upon the propriety of my determination relative to possible storage at Lake Cheesman. Even though no such mistake had been made, if, as a matter of fact, the year 1913 did not fairly represent the average year in respect to conditions affecting irrigation, that also would materially influence the justice of my conclusions.

After having estimated the demands of the ditches upon the canon I applied that determination to the stream flows. The stream flows so used are given in Exhibit 44, page 3, table 4, for the main stream below the forks, and in Exhibit 44, page 4, table 5, for the south fork at Cheesman. Where in any particular month the excess of discharge at the canon, in acre feet, over the demands, in acre feet, for the month, of ditches was less than the discharge for the month, in acre feet, at Cheesman, nevertheless Cheesman was permitted to store only the quantity of such excess.

I assumed that the year 1913 was a fair year upon which to base these estimates; I assumed that the actual diversions in that year represented the average demands; that the conditions surrounding and influencing the quantities of such diversions were as good as or better than average and normal conditions. I assumed that the accretions to the main stream from tributaries and seepage in Districts 8 and 2 in 1913 represented what could reasonably be expected as the quantity of such accretions in each and every year. I assumed that the year 1913 presented conditions which would render such accretions from seepage and tributary inflow in that year as great as, if not greater than, the average.

In this respect precipitation is an important consideration. The more precipitation, the less diversion from the stream by the irrigator. The precipitation at Denver would fairly represent the average precipitation in Districts 8 and 2. As to precipitation, it
736 is necessary to take into consideration not only the total quantity for the year, but also the quantity in each month, and further to consider the particular month in which the growing of crops is occurring.

The high precipitation which occurred in the month of December, 1913, should be excluded from consideration. Crops are growing and have more need of water in the months of May, June, July and August, principally the months of May, June and July, and the precipitation in August may benefit materially in maturing crops. The precipitation in September is of less importance. As appears from Exhibit 44, page 1*b*, in 1913 the precipitation in April, May, June and August was much below normal, and in July slightly above; the normal being 1.62 inches, the actual in that year 1.76

inches. That situation would increase the diversions of ditches for irrigation purposes above the normal. In the months April to August, both inclusive, 1913, the total quantity of precipitation was about 23% below normal.

In years of abundant and constantly maintained flow the temptation is great, and the practice exists, for ditches to divert really more water than they need. If the year 1913 was a year of full flow in these crucial months of irrigation and of the raising of crops, and the flow was well maintained, it is very possibly true that the diversions by these ditches were made in really greater quantities than their needs actually require. Nevertheless, my point of view was that the actual diversions for 1913 would fairly indicate the demand in the future, because of a possible increase in needs in future years under those ditches, and possible changes in some of the decrees. The condition of the stream flow which existed in 1913 doubtless offered a temptation to the ditches, and as a consequence the ditches very likely yielded to the temptation, to divert more water from the river than they actually needed for that year.

Exhibit 44, page 3, table 4, shows that in 1913 the discharge of the stream in the months of July, August and September was considerably above the average. The months of May and June are somewhat below the average, but not by as great a percentage as the other months mentioned are above the average. Moreover, in May and June, 1913, the precipitation was much below the average. The saturation of the ground from the previous year would have a material effect upon the amounts diverted in the months of April and May, but possibly not later than that.

The weather, temperature and the existence of dry hot winds have an effect upon the quantity of diversions in the direct flow
737 ditches. The conditions would also affect the question as to whether ground saturation would be carried over from one season to the next.

As shown by Exhibit 44, page 1, the precipitation in September, October and November, 1912, was above normal, but at the end of November it began to drop off, and in December it was 25% below normal and that January, 1913, was below normal, February above, and March approximately one-half normal.

As to the diversions of the ditches in 1913, I took my information from the commissioners' reports, mostly from the commissioners' note books that are on file. These are the commissioners' field books, which are filed at the end of the season in the State Engineer's office.

Exhibit 44, page 8, table 10; amounts compiled from water commissioners' annual report. Most of this work done by two assistants. I examined and checked them in places, but some of these details I cannot answer offhand. I think the data tabulated in table 9 is taken from the filed books and that in 10 from the water commissioners' annual report.

In these tables embraced in Exhibit 44 I have to a very large extent relied upon the accuracy of the tabulation by my assistants. I do not really know from what exact sources my assistants have

taken these figures, except that they were taken from some of the commissioners' records.

In determining ditch diversions the water commissioner or his deputy should visit each ditch practically every day. As to whether in actual practice they really do so I cannot say.

I was deputy state engineer under Mr. Field in 1897, 1898 and part of 1899. I assisted in preparing the form for the first field books to be used by the water commissioners. We hoped that the result would be to encourage greater fidelity and accuracy on the part of the water commissioners. Something of that sort was needed. It is possibly true that the statements of water commissioners about various matters relating to things which they report upon are not noted for accuracy.

It is difficult to estimate the fair average duty of water, measured at ditch headgates, in District 8 and 2. I might say that approximately three acre feet per acre per annum would be such average duty for both of these districts.

In the month of Jan., 1912, I testified as a witness for the City in the case of the New York Trust Company against the City and County of Denver, in which the Water Company was cross complainant. In that case I testified under oath, in substance (exact quotation in original transcript), that one acre foot of water would

738 in this locality irrigate about half an acre of land quite well, three quarters of an acre fairly, and an acre rather poorly.

That represented my views as to the duty of water delivered at the land, and I think I had in mind new lands, that is, lands not hitherto irrigated. Such new lands require more water per acre. The meaning of my statement in that testimony was that one and one-third acre feet per acre per annum would be a sufficient supply to irrigate fairly, where delivered at the land.

I have testified here that as an average for Districts 8 and 2 three acre feet per acre per annum is necessary, delivered at the headgate. I estimate a loss between the headgate and the land of something like 35 or 40 per cent on the average, therefore my estimate according to my present testimony means about two acre feet per acre, delivered upon the land.

On direct examination in the present case I have testified in respect to Lake Marston that the duty of water from the reservoir would be two acre feet per acre per annum, delivered at the reservoir. Under that statement, the duty of the water at the land is to be ascertained by deducting all losses intervening between the reservoir and the land. I made that statement because if the irrigator has to pay the price which would be charged for the water from the reservoir, he is going to see that the loss is small. I admit that it is the duty of every irrigator, whether he takes his water from a reservoir or directly from the flow of the stream, to use the same care to make the water perform just as efficiently in either case in order that others whose appropriations are junior to his may get what they are entitled to from the stream. Nevertheless, I do not think that in determining the question of demand on the canon to be supplied before Cheesman can store, we ought to measure that demand, not

by actual diversions made by the ditches without regard to whether they actually need it or not, but according to the quantity which such ditches ought to take and apply to a beneficial use in an efficient and economical way. I think we should be governed by practical conditions as we find them. I am undertaking to say that the law will permit these ditches to divert more than they really need for the purpose of irrigating the lands under them. That is my judgment of the law of administration. The decree, which specifies the rate of flow, does entitle the ditch to take the water up to the quantity of the decree, so far as it be used for beneficial purposes, and the question as to whether the use is beneficial or not hinges largely upon the judgment of the user himself. I regard the judgment of the user as practically the controlling factor upon the question as to whether the water is being used beneficially or not. That is my conclusion as to what the law sanctions, under the laws and the decrees.

739 Assuming, as I did in my direct testimony, a duty of Lake Marston water of two acre feet per acre per annum, measured at the outlet of the reservoir, then in determining the duty of that water at the land all losses in transit would have to be deducted. Such loss amounts in general on the average to about one-third.

In my direct testimony in this case, speaking of the yield of the Bear Creek rights and their value, I stated in substance that the water could be utilized practically upon the basis of about 1¾ acre feet per acre. That represents the duty of the water as measured at the reservoir.

In my direct testimony in this case I stated in substance, in respect to Lake Cheesman and the water stored therein, that approximately two acre feet per acre of water, at the outlet of the reservoir, would be required for the irrigation of any lands likely to purchase that water under any of the existing ditches near or below the city of Denver. That was upon the assumption that the water would be purchased for the higher lands in Districts 8 and 2, instead of for the valley lands. Such as the lands under the Highline ditch. Such water would have to be conveyed in the South Platte river from Cheesman to the intake of the Highline ditch, then about 40 or 50 miles, or perhaps more, through the Highline ditch. No one can say what the loss in the river would be. My impression is that it would be less than five per cent—three to five per cent. The loss in the Highline for an average distance of 50 miles would be from 25 to 30 per cent, making a total loss of approximately 33 1/3 per cent. So that out of that two acre feet, as measured at Cheesman reservoir, we would get to the land approximately 1 1/3 acre feet. That would irrigate the lands fairly well.

In my estimates I have dealt with Cheesman lake and the other reservoirs of the company as a direct irrigation ditch would be dealt with—that is, as the sole source of supply, as distinguished from a merely supplemental supply. As to the waters to be stored in Lake Marston, I assumed that a portion of these would be diverted on lands in the Henrylyn district. The total loss on these between the reservoir and the lands would be perhaps 40%. There would remain out of the two acre feet per acre which left the reservoir very

little over one acre foot per acre. I assumed that these lands would have some other supply. My impression is that the Henrylyn would be very glad to get new water.

The duty of water must take into consideration the precipitation falling upon the land. Such a minute element as dew fall enters into the matter.

740 Exhibit 44, page 8, tables 9 and 10—diversions of ditches in District 8; and pages 9 and 10, tables 11 and 12—diversions of ditches in District 2: these tables were collected and tabulated by my assistants. I do not know of my own knowledge whether these figures as reported by the water commissioners were the result of actual measurements or mere estimates. I think my assistants took most of the figures from the field books of the water commissioners. I have made no comparison of these figures with the original sources of information, and do not know of my own personal knowledge whether my assistants have correctly set them down. I accepted these reports of the water commissioners as measuring the needs of the ditches without any regard to what duty of water these diversions showed, also without regard to my own opinion as to what would be the proper duty of water under the circumstances, and, in fact, without any consideration of that feature of the matter.

Take for illustration Exhibit 44, page 8, table 9—Nevada ditch: the table shows that during all of May the ditch was diverting each day at an average rate of 46.1 second feet, and that during all of November it was diverting each day at the rate of 7.3 second feet, continuous diversion, and that for the months June to October inclusive it diverted constantly at a rate of 55 second feet. Table 10 shows that the ditch diverted constantly from May 6th to November 4th at the rate of 55 second feet, which in table 8 is given as the rate on the maximum day. I think it is possible that in 1913 the Nevada ditch diverted at the rate of 55 second feet continuously for 183 days. I should say this was probably a very extravagant use of water if it was all put upon the land; so extravagant upon the face of it that I think I should call it a wasteful use. That diversion means about 2 acre feet per acre per month of the irrigation season for the acres under the ditch, or a total for the 183 days of approximately 20,000 acre feet. That means a duty for the acres under the ditch of over 12 acre feet per acre. That was an extravagant and wasteful use if that amount of water was applied to the lands. Nevertheless, I think the Nevada ditch under its decreed priority has the right, as against the claim of Lake Cheesman, to take such quantities of water as that from the stream. It is upon that assumption as to what the law is that I have prepared these exhibits and given my testimony in this case respecting possible storage at Lake Cheesman. The amount diverted by the Nevada ditch in 1913 was more than twice as much as its diversion in 1912, and greatly exceeds the quantity diverted by that ditch in any other year of its history, since 1889. It is about twice as much as the average quantity

741 of water diverted annually during the full period from 1889 to date. There has been no marked variation in the acreage under the ditch since 1909. As shown by Comstock's Exhibit A-52,

table 3, the duty of water under that ditch has been as follows: 1909, 4.94 acre feet per acre; 1910, 6.29 acre feet per acre; 1911, 7.85 acre feet per acre; 1912, 4.68 acre feet per acre; 1913, 12.30 acre feet per acre. Still I do not think there is anything the matter with the data which I obtained respecting that ditch for the year 1913. I see no reason to conclude that the ditch did not really divert such a quantity of water in that year. I think it remarkable that there should have been so much more diverted by the ditch in 1913, but still, so far as the figures themselves go, I see no reason to doubt their accuracy. I nevertheless propose to allow that quantity of water as a standard allowance against Lake Cheesman for the Nevada ditch before Lake Cheesman can store, and, all things considered, believe it justifiable. The average annual diversion of the Nevada ditch for the four years preceding 1913 was 5.8 acre feet per acre per annum. By taking the reported diversion for 1913 instead of that average I have increased the charge against Lake Cheesman, which must be filled in each and every year before Cheesman can store, by the amount of 10,000 acre feet annually. Nevertheless, takin all things into consideration, I think the assumption that the use in 1913 would constitute a fair measure of demand for the future is a fair one.

Exhibit 44, page 8, table 9—Last Chance ditch; shows diversions for June and September at the rate of 28 second feet, and at less rates for all of the other months, with the statement that the maximum daily rate was 28 second feet. Table 10, however, shows an average rate for 155 days of 28 second feet, and that diversion began on May 7th and ended on October 20th. Table 10 appears to be inconsistent with table 9; I cannot tell why. I understand it to be a copy from the report of the water commissioner. Tables 9 and 10 are inconsistent. I could not at this time say which is correct. According to table 10, the Last Chance ditch diverted in 155 days, 8,680 acre feet, a duty of 7.8 acre feet per acre for that year. According to table 9, the total diversion was 8,381 acre feet, and the duty 7.62 acre feet per acre. According to Exhibit A-52, table 7, the diversion of the Last Chance ditch in 1912 was 7,254 acre feet, making a duty of 6.51 acre feet per acre. 1912 was a year of full flow. Presumably they utilized all of the water they needed in that year. But in 1912, on account of rains in the summer, there was a very marked falling off of use of water in a great many of the ditches. It was not by any means a year of normal demand in some
742 months. The amount taken into ditches in 1912 was less than the normal for the years both before and since.

I do not think I disagree with my partner, Mr. Field, as to the year 1912. It is true that in 1912, although it was a year of large flow, Mr. Field did not permit Cheesman to store to its full capacity, as appears in his Exhibit 30. I did. The basis used by Mr. Field and that used by me are not the same. I say that these ditches diverted less than the normal in 1912. I do not think that he went into it quite so far as I did.

As to the Last Chance ditch; if the records show that in 1909 the ditch diverted 4,167 acre feet, with a duty of 4¾ acre feet per acre; that in 1910 the quantity diverted was 4,771 acre feet, with a duty

of 4.70 acre feet per acre; that in 1911 the quantity diverted was 5,076 acre feet, with a duty of 4.77 acre feet per acre; that in 1912 the quantity diverted was 7,254 acre feet, with a duty of 6.51 acre feet per acre; that for those four years the average quantity diverted annually was 5,317 acre feet, with an average of 5.1 acre feet per acre; and that in those four years the average acreage irrigated was 1,039, as compared with 1,100 in 1913; and that in 1913 the ditch diverted 8,680 acre feet, as compared with the average of 5,317, making a duty of the water of 7.9 acre feet per acre, as compared with the average of 5.1 acre feet per acre; I would think from the appearance of that that in 1913 the ditch probably diverted more water than they actually needed or required for crops that year. As compared with the average, that excessive diversion in 1913 was approximately 3,000 acre feet.

Taking only the Nevada and Last Chance ditches, in District No. 8, it appears that the excessive quantity diverted in 1913 by the Nevada was 11,000 acre feet, and by the Last Chance 3,000 acre feet, a total of excess diversions for those two ditches alone of 14,000 acre feet in 1913. This I have used as a constant quantity, charging it up year by year for all this series of years against Lake Cheesman, prior to any storage in Cheesman. That was an error, unless there were features that more than balanced it. Unless some features existed which balance and offset said error, then the opportunity of Cheesman to store for each of these years which I have considered ought to be increased on the average for each year about 14,000 acre feet.

Exhibit 44, page 8, table 9—Highline ditch: The information tabulated in tables 9 and 10 came from the water commissioners' reports. I did not myself look at all of the water commissioners' reports in respect to the Highline. If the water commissioner's annual report states that the Highline made a diversion at an average rate of 193 second feet for a period of 116 days, which would produce
743 a total of 44,742 acre feet, instead of 62,664 acre feet as my tables 9 and 10 show, then there is a serious error in my estimate in charging up such a quantity of water as that to Lake Cheesman, to be allowed each year on account of the Highline ditch before storage is permitted in Cheesman.

In 1913 the Highline and the Antero reservoir were being operated together. On that account more acres were broken for cultivation in that year than the average acreage. I heard Mr. Bull's statement that on the average the acreage irrigation from the Highline was approximately 20,000. According to my Exhibit 44, page 8, table 10, the acres irrigated in 1913 were 28,000.

I do not think it was proper to include in the diversions of the Highline, and to charge against Lake Cheesman before storage could occur, the quantities which in 1913 came down from the Antero reservoir and were diverted into the Highline to irrigate the additional acreage. I have seen a statement showing the quantity of storage water sent down from Antero and diverted into the Highline in 1913, but I did not examine it with respect to the tabulation in Exhibit 44, page 8. Nevertheless. I assumed that the quantity diverted

by the Highline in 1913, including said storage water, was a fair measure as to what the ditch would in future divert. It is true that storage waters from Antero reservoir diverted by the Highline in 1913 are not to be charged against Cheesman's right to store. If I have done so in this particular instance, that constitutes an error in my determination, unless other considerations exist to offset it.

I did not examine the annual report of the water commissioner for the purpose of finding out the facts concerning diversions through the Highline in the year 1913. If that report showed that for a period of forty days the ditch was diverting storage water, presumably from Antero, in a total quantity of 21,920 acre feet; and if the reasonable demands and needs of the ditch are to be measured by its diversions from direct flow in the year 1913, then the quantity of storage waters so diverted ought not to be charged up as a demand to be filled before Cheesman can store.

The field books of the water commissioner are expected to show his actions from day to day, including the facts relative to the diversion of ditches. I looked over the field book of the water commissioner in District 8 for the year 1913. I do not remember whether I found in that field book any statement as to the rate at which water was being diverted at any particular time in that season by either the Nevada or the Last Chance. Nor do I remember whether the only mention made of the Nevada or the Last Chance, as to their
744 respective rates of diversion, appears at the conclusion of the season, when a statement is made as to their average diversions, of 55 and 28 second feet, respectively, during the season.

Exhibit 44, page 8, table 9—Nevada ditch: Although it did not begin to operate until May 6th, the average rate of 55 second feet is in the table apportioned over all the days in May. The same thing is done in November. A similar process occurred as to the Last Chance. By that process, in the case of the Nevada ditch, I prohibited Cheesman from storing in the first five days of May and in the last twenty-six days of November because of the demands of the Nevada ditch, when as a matter of fact no such demands existed. The fact that the Nevada ditch diverted water at the rate of 55 second feet in the first four days of November does not indicate that it desired or needed to divert at the rate of seven and a fraction second feet for all of the following 26 days. Nevertheless, I do not think that the method which I adopted would, on the average, throughout a long period of years, make any difference in the result as to storage in Lake Cheesman.

The way in which the diversions of the Nevada and Last Chance ditches were reported in the field book of the water commissioner in 1913 indicated that the commissioner did not visit them during the season, or that he did not know the amounts of water that they were actually diverting from time to time, so as to include them in his weekly and monthly reports, or that at the end of the season he simply made the statement which he did because he knew that throughout the year they had received all of the water they wanted, or that he knew that they were carrying approximately their decreed capacity throughout the season. I do not know who the water com-

missioner of District No. 8 for the year 1913 was. I do not follow those matters very closely since I severed my connection with the State Engineer's office. I did not know that said water commissioner in that year was a new man, who had had no previous experience, and that his appointment occurred rather late in the irrigation season, his first report being for the week ending May 10th, although these facts are obvious from a consideration of his weekly reports. Nevertheless, I simply took the reports as to the use of water as the basis of my determination. If the facts stated above are correct, the probability is that a man of that sort had little knowledge and little experience in the measurement of water. Knowledge and experience are required for that purpose, and also required to estimate with any degree of accuracy the inflow of water. In that particular year, the first year of his experience, such a man would be likely to make mistakes in his estimates of flow or in his measurements of diversion by the ditches. He would be likely to
745 make mistakes in his estimates of inflow from tributaries and seepage. Considering the way in which the water commissioner reported the diversions of the Nevada ditch and the Last Chance ditch at the end of the season only, it would be the natural inference that he had failed to visit those ditches during the season, or had been unable to estimate or measure the flow into the same, and had made a sort of an estimate of an average at the end of the season. Such estimates are likely to be in error.

I did not know what devices the Nevada ditch was supplied with for wasting back into the stream the water diverted at the headgate, and did not know that it was the custom of that ditch to maintain a constant head and to waste the water back in-o the stream at these various discharge points. I think it likely, however, as that is the ambition of almost every ditch. Thereby they get the water back into the river in time to meet the needs of the next diverter below. But the water so diverted by the Nevada ditch and afterwards wasted back into the river would be included in the water commissioner's report of diversion by that ditch.

I believe the Last Chance ditch is similarly provided with waste ways, and I think it likely that they operated in a similar way—that is, they take in the full capacity at the headgate and waste it into the river in time to meet the needs of the next diverter below. That would be counted as a diversion for the first ditch which takes it out, and also counted as a diversion by the ditch which again diverts it below. It does appear in the water commissioner's reports of diversion, which I have made use of. I have not considered the duty of water which these respective diversions of ditches in District 8 for 1913 would show. It is true that that duty would be as follows: Platte Water Company, or City ditch, 7.64 acre feet per acre; Nevada ditch, 12.30 acre feet per acre; Petersburg, 6.72 acre feet per acre; Platte Valley, 8.45 acre feet per acre; Brown, 8.05 acre feet per acre; Last Chance, 7.89 acre feet per acre; Green Valley, 13.20 acre feet per acre; Northern Colorado Irrigation Company (Highline), 2.24 acre feet per acre. All of those duties are very much lower—that is, amount to an application of a very much greater

quantity of water per acre, than any testimony which I have given as a proper application, either in this case or in the New York Trust Company case, with the single exception of the Highline. The Highline, however, covers most of the land.

Exhibit 44, pages 9 and 10, tables 11 and 12—diversions by ditches in District No. 2: As in District 8, some of the ditches in 2 are provided with appliances for wasting the water back into the river, and are operated by diverting a steady flow at the
746 headgate and wasting it back into the river for the use of the next consumer below. As a result of that, there is a doubling up of quantity of water actually used to irrigate crops, in that the diversion of the same water is counted twice. Nevertheless, I have used the figures of diversion as reported by the commissioner.

The decree of the Jay Thomas ditch has been reduced from 104.35 second feet, as stated in table 11, page 9, Exhibit 44, to 18 second feet. Under that ditch, according to my exhibit, the duty of water in 1913 was 13.6 acre feet per acre. I do not think there are any garden tracts under the Jay Thomas ditch.

Exhibit 44, page 10, table 12—the Burlington ditch: The diversions shown would produce 85,652 acre feet, making a duty of water under that ditch of 5.73 acre feet per acre. I do not know how much of that water was diverted by the Burlington under its direct flow rights, and how much for purposes of storage. Its only storage decree prior to Cheesman is for Barr Lake, amounting in total quantity to 11,000 acre feet, with some addition for loss by seepage. The addition for loss by seepage would bring the total for Barr Lake up to approximately 16,500 acre feet. The water commissioner is presumed to report what quantity is diverted by each ditch for storage purposes. The figures appearing opposite the Burlington in table 11, Exhibit 44, for the months of January, February, March, April, November, December, and part of October are quantities which the water commissioner reported as having been diverted for storage.

In District No. 2 diversions for storage are made both for decreed and undecreed reservoirs which are subsequent in time to Cheesman. According to my table, the diversions made by the Burlington in January and March would yield 11,916 acre feet, which is more than is necessary to fill Barr Lake's priority. The diversion made in April would furnish 13,500 acre feet, which could not have been on the original priority of Barr Lake. I think it was important to determine whether these diversions were made for storage or for direct irrigation, but I did not make that determination. If in fact the Burlington's diversion in April was for storage purposes, it must have been upon an appropriation junior to Cheesman. The note at the foot of table 11, page 9, Exhibit 44, could not have referred to other ditches having prior appropriations for storage purposes, because there are none such. The persons who compiled this information for me stated that the amount diverted for storage purposes could not be segregated from that diverted for direct flow rights. If the water commissioners' reports show otherwise, that was a mistake.

747 Exhibit 44, page 9, table 11: The diversions by the Burlington in October, 1913, would yield 17,573 acre feet, which was presumably for storage, and the large drafts made in November and December were likewise for storage purposes. Those must have been upon an appropriation junior to Cheesman, unless they were placing the same in Barr Lake for the next year. Even if they were doing that, they would have filled Barr Lake in October, and diverted 6,583 acre feet in addition. The 17,000 acre feet, approximately, diverted in October alone, if wrongfully charged against Lake Cheesman, would entirely eliminate the canal demand upon the canon for the month of October, as stated in table 14, page 12, last column, month of October.

Without calling specific attention to the various canals in Districts 2 and 8, the matters so far brought to my attention are such that I do not believe I could, without giving the question further consideration, say whether or not we are likely to arrive at just results by taking as the absolute measure of the real needs of these ditches the diversions made in the one year, 1913, as reported by the water commissioners and as incorporated in these tables. The matters already suggested certainly have an important bearing upon that question. But they are not enough as yet to make me think that the assumption is not a fair assumption. That is because I have in mind some compensating features which must offset any overestimates of demand or other errors which may occur in respect to this method of arriving at the real demand. Those compensating features are as follows: (1) the Lupton Short Line ditch, with a decree intervening between the two decrees of Lake Cheesman; (2) the changes in the decree of the Fort Morgan Land and Reservoir Company's canal; (3) the distance from Lake Cheesman to the points where the demands arise; (4) the flattening out of the peak floods, and the seepage of water in the bottom lands and valley lands; (5) the fact, discussed yesterday, that recorded flows at the canon exceed the actual flows to some extent, which fact had a little weight with me; (6) the surprisingly small demand of the Burlington ditch in the summer months of 1913; (7) the small amount of diversion in April; (8) the fact that the actual capacity of Lake Cheesman is less than that reported, on account of its filling to some extent with silt.

The decree of the Lupton Short Line is of July 6, 1892, for 72 second feet; its actual capacity to divert is something like 25 or 30 second feet, according to my recollection. But I have a memorandum here that its capacity is 70 second feet. I have already re-

748 ferred to the Lupton Short Line as offsetting my failure to permit Cheesman to store on the peak floods. I have not made any exact computation to determine whether the plusses and minuses in my estimates offset one another.

The canal of the Fort Morgan Land and Reservoir Company is in District No. 1. Its decree was recently increased by about 300 second feet, as of date 1888. It is impossible to say to what extent a demand of that sort down at Fort Morgan would be reflected on the right to store at Cheesman. It would have an important bearing.

In my computation I made the assumption that so far as District No. 2 was concerned, the demands of District No. 1 would be satisfied by the inflow of certain tributaries. I think that assumption rather more favorable to Lake Cheesman than was actually warranted by the records; how much more favorable I do not know. I am unable to say that the errors I have made against Lake Cheesman are offset by the errors I have made in its favor. No engineer who is experienced in these things assumes that his figures are absolutely correct.

As to the distance of the ditches from Lake Cheesman and the flattening out of the floods, I have already used that as a factor offsetting my failure to permit Cheesman to store on the peak floods.

As to the possibility that the measurements of the flow at Platte Canon may have exceeded the actual flow, because of the rocky and boulder filled bed of the stream, I do not know the extent of such excess, if any, and I do not know what measurements of that sort are justly subject to that criticism. Moreover, I have already used that as a factor to offset my failure to permit Lake Cheesman to store the peak floods.

As to the small diversions of the Burlington during the irrigation season of 1913; for the purpose of my computation I assumed with respect to all of the ditches that their diversions in 1913 represented what they on the average really needed. I have no figures on the diversions of the Burlington ditch during the last several years. They usually fill Barr Lake, and make some diversions in addition to that for direct irrigation. I did not know that for the last four or five years the quantity of the average annual diversion of the Burlington, including the filling of Barr Lake, has been about 20,000 acre feet. I did not know that in the year 1913, including the filling of Barr Lake, the quantity diverted for direct irrigation was approximately 22,000 acre feet. Those figures would not show that there was any less diverted for direct irrigation in 1913 than had been drawn on the average in previous years. I could not say how many of the acres under that ditch are put into cultivation in reliance upon water to be diverted under priorities later than
749 Cheesman. I had no other information upon which to base my statement that in 1913 the Burlington drew less than it usually needed.

As to my statement that the diversions of the ditches in April 1913 were less than they usually are: the Highline usually draws in April; the records of a number of years show that less than five per cent of the water drawn in District No. 2 in each year was drawn in the month of April. I have made no investigation or examination to determine how much, if at all, the draft in April, 1913 was less than the usual quantity diverted in that month in other years.

As to my statement that the capacity of Lake Cheesman as recorded has been decreased by reason of silting: No one can say to what extent. I think it has been at least—others said from two to three hundred acre feet; I do not know. There is some capacity in Lake

Cheesman below the outlet, not included in its rated capacity. This is about 75 or 100 acre feet.

Even though the rated capacity of Lake Cheesman has been decreased 300 acre feet by reason of silting, it would not affect my estimate of the storable quantities on the various assumed drafts, except when the reservoir was standing full. Still the shortage in real capacity of the lake produced by silting, even to the extent of 300 acre feet as stated by me, would have an effect upon possible storages. I do not think that effect would be so small as to be negligible.

Exhibit 44, pages 9 and 10, tables 11 and 12—diversions of ditches in District 2: I do not know whether the Union ditch is the intake for the Lower Latham reservoir, but would have thought that it was. According to the figures given in table 12, the diversion of the Union ditch 1913 resulted in a duty of more than 5 acre feet per acre. On the basis of those figures, that is a low duty. If the Lower Latham reservoir was filled in that year, I cannot be sure that this quantity includes water diverted for the reservoir. I did not look into that point in making this estimate. That duty of water indicates an unusual and unnecessarily large diversion for the number of acres under the ditch, for direct irrigation. The appropriation of the Lower Latham reservoir is junior to Cheesman. The notes prepared by my assistants do not indicate whether the diversions made by the Union ditch, or any part thereof, were or were not for storage. I have not myself examined into that particular point.

Exhibit 44, page 10, table 12—Evans No. 2 ditch; that ditch is the conduit which conveys water from the river to Milton lake. In 1913 some water was diverted for storage in Milton lake; I do not know how much; I have not specially investigated that question in connection with getting up this table. I do not know
750 how much of the water diverted by the Evans No. 2 ditch in 1913 was diverted for storage in Milton lake. The storage right of Milton lake is subsequent to that of Cheesman.

If as a matter of fact a part of that water was diverted through the Union ditch for storage in Lower Latham reservoir, and through the Evans No. 2 ditch for storage in Milton lake, such diversions, being on rights junior to Cheesman, ought not to be charged up against Lake Cheesman storage. That would be true if you were trying to reduce the matter to the utmost detail. In arriving at average conclusions I think it ought to be so charged, taking into consideration the fact that the duty of that entire district appears to have been less than 3 acre feet per acre.

It appears that I have not taken as the measure of the needs of the ditches the quantities diverted for direct irrigation, but have taken such quantities plus considerable quantities diverted for storage on later priorities than Cheesman. I call 17,000 acre feet, so included in the month of October in the case of the Burlington ditch, a relatively small amount.

Referring to the note at the foot of table 12: Section No. 3 ditch has no connection whatever with the Burlington.

There is some confusion in the commissioners' reports. I cannot explain this any more than I did before.

As to the Nevada ditch, in District 8, the water commissioner's field book for 1913 gives May 7th as the first day on which water was diverted, and his annual report gives May 17th as such date. My tables disclose a number of inconsistencies and inaccuracies in the water commissioners' reports. Nevertheless, I do not think that the water commissioners' reports are conspicuous for the erroneous and loose statements which they contain.

As to the amended decree of th Fort Morgan ditch, referred to as a compensating feature to set off against mistakes made against Lake Cheesman: I have not visited that ditch for ten or twelve years. The intake is about 20 miles below Kersey, probably 24 or 25 miles below the lower boundary line of District No. 2. It is some distance down into district No. 1. It is on the East and South side of the river. I have not the details of that decree, and do not know whether the additional quantity decreed is for direct irrigation purposes or for storage. If it be for direct irrigation purposes, manifestly there must have been a diversion of that sort going on by that canal for some considerable period of time. As the decree relates back to 1888, the use of water must relate back to the same date; otherwise they could not have obtained such a decree,
751 unless they had very skillful lawyers. They could not do it unless the lawyers succeeded in fooling the court.

As to deduction from total diversion to arrive at demand upon the canon: After having arrived at the total of the diversions in Districts 8 and 2, I first deducted all of the estimated inflow from tributaries and seepage in District No. 8, as shown by Exhibit 44, page 6, table 7. That table is made up from the weekly reports of the water commissioner, except quantities marked by stars, which are estimated by me. We should also put a star after the quantity of inflow from Bear Creek in April, also Cherry Creek, and seepage for April; likewise, January, February, March and December. Out of the 48 entries appearing in said table 7, 20 have been estimated by me. Those estimates were based on a few known flows, and by comparisons with the rest of the table. As they do not enter into the conclusions any way, reasonable amounts were set down to fill out the table. Those estimates were made by my assistants and referred to me for final approval. No measurements were made. So far as I know, the commissioners have never reported upon the stream flows of any of these tributaries in District 8 for the months January, February, March, April and December in any year. Even the figures for tributary inflow reported by the water commissioners in Districts 2 and 8 are mere estimates and not measurements.

As between Cherry Creek inflow and seepage, I do not know how much is attributable to each. It is my understanding that the water commissioner reports them together. Cherry Creek has an extremely variable flow. It is subject to floods. There are floods in almost every season, sometimes very heavy and destructive.

It is true that there are so many stars on this table 7 that it looks

like a considerable constellation. All of the figures are estimates, estimated either by my assistants or by the water commissioners.

In addition to deducting seepage and tributary inflow in District 8, I also deducted from the gross diversions of the ditches the seepage in District No. 2 and the inflow from Clear Creek, both as estimated by the water commissioner. I left out of consideration all other accretions to the stream in District No. 2.

As to district No. 2, these matters are tabulated in Exhibit 44, page 5, table 6, and page 7, table 8. The figures are taken from the weekly reports of the water commissioner. The figures are the result of his estimates, and not of measurements. As here used, seepage covers sewage from Denver. That also is an estimate by the water commissioner. Sewage varies from year to year, as the use of water varies in the city of Denver. Less water was
752 used in Denver in 1913 than in 1910, nevertheless, I am inclined to think 1913 measures what will be the average use in future years. As the town grows the use will be increased, unless the meter system is installed. If present practices continue, the use will increase, and the sewage will increase accordingly. Nevertheless I think it fair to take the actual quantity of sewage in 1913 as the measure for the future, because we make no allowance for the use of additional amounts of water under existing decrees. That is an additional factor which I have in mind as an offset against any injustice I may have done to Lake Cheesman in these estimates. Cheesman have a right to greatly and materially extend the acreage I have no doubt that these old ditches having priorities earlier than which they have during this long period of years been serving, and so increase their diversions for the purpose of serving these new lands, as against the right of Cheesman and other subsequent appropriators. I had this in mind as an offset to any possible injustice I might do to Cheesman by my method of determination.

As to accretions in District No. 2, I have allowed all tributary inflow except Ralston and Clear Creeks to go to District No. 1. There are a large number of tributaries in District No. 2 aside from Clear Creek, but most of them return little but seepage. My assumption was that on the average these tributaries other than Clear Creek would furnish enough water to supply District No. 1.

Exhibit 44, page 5, table 6, deals with the St. Vrain and the Big Thompson only. The table was prepared to show that the amounts reported as inflow from those two streams approximates in amount the quantity reported as outflow from District No. 2 to District No. 1. The table is simply illustrative. I do not necessarily derive from it the conclusion that all of the inflow from the St. Vrain and the Big Thompson is needed all of the time to supply the ditches in District No. 1, nor that the ditches in District No. 2 are not entitled to take it at all. Nevertheless, I have made the assumption that on the average that would be the condition. Said table No. 6 covers figures for these inflows as reported in the weekly reports of the water commissioner—they are estimates. Said table covers only the period May 10th to September 20th, although my tables in respect to other tributaries covered the entire calendar year. I

cannot say positively why that is. Apparently the water commissioner in District 2 reports these inflows for the entire calendar year. Table 6 might have been extended to cover the irrigation season.

753 Both in May, and also in September and October, as appears from table 14, Exhibit 44, I have charged up large deficiencies in respect to the demand of ditches not supplied by seepage and inflow, but which must be supplied from the canon, nevertheless I did not think it was necessary to consider the inflow from the St. Vrain and the Big Thompson during those months, although that inflow might have been large. But if, for example, in the month of October the demand in District No. 1 was entirely supplied from sources other than these two tributaries, then the demand of District No. 2 ought to be lessened by the accretions from the St. Vrain and the Big Thompson. But I would like to look into that matter a little further. I do not think it is obvious. If the accretions from the St. Vrain and the Big Thompson in October amounted to 11,000 acre feet, this added to the 16,900 acre feet diverted by the Burlington in October for storage, under a priority junior to Cheesman, would practically balance the demand on the canon for irrigation diversions in the month of October, as shown by Exhibit 44, page 12, table 14.

The streams in this region are extremely varying in their flow. Not only does each stream vary from year to year, but they vary from year to year in their relations to one another in respect to stream flow. The tributaries which enter Districts 8 and 2 have their headwaters along the mountain range, through a wide region, extending from the South Park up to the Wyoming line. The condition at the headwaters of these various tributaries, as to snow, rain, temperature, etc., have a great deal to do with the condition of the stream flow. These conditions vary greatly in the different water sheds of these different streams. Nevertheless, I took absolute conditions as they existed in the year 1913 for building up the absolute quantity to be each year charged against Lake Cheesman. I determined from all the data that I had at hand that that year would fairly represent average conditions.

It is true that in the case of the New York Trust Company vs. the City and County of Denver I testified in substance as follows (exact quotation in original transcript): that for the purpose of determining the amount of water available I did not consider it fair to take the mean flow of the stream for one year, or for a period of ten years, but that all the figures possible ought to be used in arriving at an estimate of the mean flow; also that when I was called upon to report upon irrigation projects and the amount of water available, I did not use the mean flow of the stream for a period of ten years or for one year, but that I ascertained the variations from one month to another, and did not confine myself to a period

754 of ten years. The streams I was there speaking of were these streams tributary to the Platte, and the reason for my testimony was the varying character of their flow. Nevertheless, in this case I have taken the record of one single year as the absolute guide

for all years. In this case I did not have before me any tabulations, nor did I examine any records, respecting the stream flows in these various tributary streams for any period of years prior to 1913.

I also testified in the New York Trust Company case (exact quotation in original transcript) that the flow of water in the South Platte varies greatly in quantity, not only month by month but day by day; in that regard conditions are the same in the tributaries. But in this case I did not use the stream flows of the South Platte and of the south fork of the South Platte as they existed in the year 1913 only in determining possible storages at Lake Cheesman. I had definite data on that subject covering a long period of years. We have no such record as to the tributaries. If we had had such data as to the tributaries, I think it should have been used in obtaining the average; nevertheless, I think I obtained fair results by using the tributary stream flows of 1913 only.

Exhibit 44, page 12, table 14, last column to the right shows demand on the canon as determined by me. I have not compared those figures with the analogous conclusion reached by Mr. Field.

Exhibit 44, page 3, table 4: Prior to looking at that table I had been under the impression that the year 1902 was the year of lowest flow in that series of years. It is generally so understood by engineers and others familiar with stream flows in this locality. A large number of quantities in this table are either built up or expanded by me from the record of a few days in the month, or else they are arrived at by me by ratio and proportion, on the theory of a supposed relation between the flow in the south fork and the flow in the main river. The expanding method is applied mostly in the winter months of January, February, March, November and December. I think stream flows in those months are more uniform than in the other months of the year. (His result for April, 1905 by the expension method compared with actual stream flows as shown in Exhibit A-27.) Manifestly there is an erroneous statement in my table as to that month.

In table 4, the figures arrived at by the application of the ratio and proportion method are marked with a star. This ratio has been computed from the figures appearing in tables 2, 3, 4 and 5, using for that purpose only those figures in table 4 taken from actual records and not estimated by me.

755 Comparing tables 4 and 5, on pages 3 and 4, respectively, of Exhibit 44, it appears that there were only nine years during which we had actual records for both streams. It also appears that there were only seven years in which we had simultaneous records for the month of January. Table 3 on page 2 shows as result of my computation, a ratio of 24% for the flow of the south fork for the month of January. Comparing the actual flows, as recorded in tables 4 and 5, for the month of January, yields the following percentages: 1900, 25.35; 1904, 3.07; 1909, 28.06; 1910, 38; 1911, 17; 1912, 19.42; 1913, 16.44. That shows a very great variation in the relation between the flows of those two streams for that period of seven years during which we have actual records. Nevertheless I have used an average percentage for the purpose of

building up the stream flows for those years when we have not actual records at the South Platte. A similar variation exists in the other months of the several years where simultaneous records exist. Nevertheless, I have taken an average percentage for each of those and appli-d it in building up stream flows.

These facts illustrate the great variation which occurs from year to year in the relation of the flow of one stream to the flow of another, even though they both be tributaries of the same main stream, also the great variation in the actual flow of the same stream from one year to another.

In building up stream flow at South Platte for January, 1902, I have taken the average percentage of 24% as the flow of the south fork, which yields a total discharge of 15,900 acre feet. I think it is quite doubtful that there was any such discharge in the year 1902. I think it probable that by that method too much was allowed for the year 1902. I think it probably true that the total quantity shown as the discharge for the year 1902 on said table 4 is erroneous, in that it is too large. But the errors occurred in such months as would not affect storable quantities in Lake Cheesman. For example, January, 1902, as shown on table 4, gives a discharge at Platte canon about three times the average for that month; and December, 1902, presents a similar situation. It is probably quite out of the question, considering the fact that year 1902 was a very dry year, that these are correct figures, being greater than any recorded flow. Moreover, applying my percentage for December, as shown in table 3, and considering the recorded stream flow in the south fork, the arithmetical result ought to have been 2,610 acre feet, instead of 17,700 acre feet. I think that must be an error. Such thinks as those I think clearly account for the fact that in Exhibit 44, table 4, 1902 does not appear to be the lowest year in point of stream flow. In that table out of the total quantity
756 which I estimated as the discharge of 1902, about 40% is covered by these estimates of mine.

Exhibit 44, page 4, table 5—discharge of the south fork at Lake Cheesman: this is derived from the information furnished to the state engineer by the Water Company. It is the only data available, and is the data which has been used by all of the engineers who have testified in his case, including Mr. Field and myself. The stream flows are reported by the Water Company, which reports are kept on file in the State Engineer's office.

Exhibit 44, page 13, table 15, shows how the various factors of my determination are applied to each of the years 1900 to 1913, giving the total available storage at Lake Cheesman in each month of each of those years, according to my estimates. I have deducted from the discharge of the South Platte at Platte Canon not only the irrigation demands, but also the needs for the direct flow rights of The Denver Union Water Company, as measured by the diversions shown in table 13, page 11, Exhibit 44. I have assumed that all of those diversions by the Water Company were upon rights prior in point of time to Cheesman. The opportunity of Cheesman to store is, of course, finally limited by the quantities flowing in the

south fork. Those quantities ascertained by me are the quantities reported by the Water Company. If those quantities are less than the actual flow, then my results are incorrect.

I have prepared these tables upon the assumption that the recorded inflow into Lake Cheesman accurately represented the actual inflow as measured over weirs on the South Fork and on Goose creek. There are other sources of supply to Lake Cheesman; for instance, Turkey creek, other canons and gulches, and possibly springs in the bed of the reservoir. There are no means of measuring the inflow from these other sources.

If as a matter of fact the inflow into Lake Cheesman as reported is determined by changes in the level of the lake, shown by a gauge rod, then the reported and recorded inflows do not represent the actual inflows. Such recorded inflows would be less than the actual inflows to the extent that there had been any loss from the lake by reason of evaporation and other causes. According to my estimate of evaporation and other losses, that amounts in the aggregate to a vertical loss of approximately five feet per annum. That would amount to a good many acre feet in the course of a year, considering the stages at which the water has actually been standing in Lake Cheesman since the lake was constructed. It would be a matter of pretty intricate balancing and careful calculation to determine how much that would amount to. According to my estimate of
757 vertical loss from evaporation and other causes of approximately 5 feet per annum, that would mean, on a full reservoir, a difference in stream flow of between 43 and 44 hundred acre feet.

My method differed from that of Anderson and Comstock in that I permitted no storage of Cheesman unless the flow at Platte Canon was sufficient at all times to at least supply the estimated demands of the Water Company for its direct diversions, whereas Mr. Anderson and Mr. Comstock in the winter months permitted storage of all the waters flowing in the south fork, thereafter deducting from the estimated yield of the Platte Canon ditch whatever quantities it had been deprived of by that method. If I had followed their method, of course my estimate of quantities storable at Lake Cheesman would have been increased.

In table 15, all figures except those appearing under the columns relating to "Excess at Canon" and "Available Storage at Cheesman" are taken from the previous tables in Exhibit 44.

Exhibit 44, page 20, table 16, is merely a statement of the available storage in total quantity for each year of the series, as exhibited on table 15, except that in table 16 for years of full supply I have limited the total available storage by the capacity of the reservoir.

The year 1914 is a year of full supply, and Lake Cheesman would have been able to fill to its capacity. The year 1899 was also a year of large flow. I think it probable that Lake Cheesman could have been filled in that year. If 1899 and 1914 had been added to table 16 as years of full supply, of course the average would have been raised.

Exhibit 44, pages 22 et seq., dealing with averages for Lake Cheesman on assumed draft of 40,000 acre feet, and also on assumed

draft of 50,000 acre feet: In each of these tables I have dealt with Lake Cheesman as furnishing water in the months May to October, inclusive, in substantially the following percentages: May 16%, June 25%, July 25%, August 20%, September 10% October 5%. That is, the use of the reservoir as a means of sole supply. I have not upon either of the assumed drafts estimated, as Mr. Bull did, what quantity would be required to be wasted over the spillway. Under the 40,000 acre foot draft undoubtedly a considerable quantity otherwise storable would so escape. I have made no estimates of the quantity so wasted. I do not think it is material. In my judgment you could get more for the water per acre foot on the basis of a 40,000 acre foot draft than on the basis of a 50,000 acre foot draft. I think the difference in the price per acre foot would be about $7. I think that on the basis of a 40,000 acre foot draft, with an efficiency of 95.6 per cent (as shown in Exhibit 44,
758 page 36) the reservoir should be able to sell water rights at the rate of $35 an acre foot, whereas on a 50,000 acre foot draft, with an efficiency of 91%, it would be obliged to sell water rights at the rate of $28 per acre foot. I made no computation to determine what price could be obtained per acre foot on a basis of a 60,000 acre foot draft. The computation which I just now made to determine the difference in price between a 50,000 acre foot draft and a 40,000 acre foot draft was an arithmetical computation, whereby I determined at what price per acre foot you would have to sell 50,000 acre feet in order to yield exactly the same total as 40,000 acre feet would yield at the rate of $35 per acre foot.

The stages of the water in the reservoir upon the various assumptions of annual draft at times when there is storable water in the stream limit the capability of the reservoir to retain and store such water. It is therefore important to so operate the reservoir, and upon such an annual draft, that to as great an extent as possible there may be space in the reservoir in which to retain these waters available for storage when they come down the stream. The quantity of water wasted out of the appropriation on an assumed draft of 40,000 acre feet is an important consideration in determining whether or not the 40,000 acre foot draft is the proper draft. I am inclined to think that before finally determining how to operate the reservoir, the practice and experience of a good many years ought to be had, and that the operation should be based upon that experience.

In my tables of operation on the 40,000 and 50,000 acre foot draft I have begun on January 1, 1900 with a reservoir half full, although, as I have previously stated, the reservoir might have been completely filled in 1899. The stream flows in 1899 were such, as shown by my exhibits, that that year, if it had been added to the list, would have given a performance of 100 per cent efficiency either on the 40,000 or the 50,000 acre foot draft, and still there would have been enough water remaining to give 100 per cent efficiency on either draft in the year 1900. The year 1914 would also have shown 100 per cent efficiency, either on the 40,000 or the 50,000 acre foot draft. By adding 1899 and 1914 as years of full efficiency the percentage of efficiency on either draft would, of course, have been raised. But I

think it would have given an incorrect average, because we begin and end with a full year.

As to the matter of evaporation on these tabulations of operation under assumed drafts: For each month I took the mean of the surface areas at the beginning and at the end of the month, and to that mean applied the factor for that month, as shown on page 21 of Exhibit 44, table 17. To ascertain the factor of vertical loss
759 for each month, I have taken the average of Cheyenne, Colorado Springs, Denver and Pikes Peake. I assumed that there was enough difference between Pikes Peak and what exists at Lake Cheesman so that the inclusion of Pikes Peak in the stations from which an average was to be taken would give what the evaporation ought to be at Cheesman, in spite of the fact that the evaporation at all of the other stations was in my judgment greater than at Lake Cheesman. I think that is a very fair way to get at it. In that way I arrived at a vertical loss from evaporation alone of 57.9 inches annually, or in feet 4.832. To that I added other losses estimated for the year to be .268 of a foot, or about 3 inches; the loss from all other causes being estimated as approximately one-twentieth of the loss from evaporation.

I have made no deduction for precipitation. Exhibit 44, table 1A, is a diagram showing the amount of precipitation at Lake Cheesman. That shows an average annual precipitation at Cheesman at 16.30 inches. I do not think loss by evaporation from the surface of the lake ought to be offset by the quantity which falls on the surface as precipitation. If I deducted precipitation, the net loss from all causes would be approximately 45 inches, or 3 feet and 9 inches. I do not make that deduction, because I think the precipitation belongs to the river. If the reservoir were not there, I do not think that all of the water precipitated would enter the stream below. I do not think it is the duty of a reservoir owner to put a roof over his reservoir. I think it is practically impossible to require the owner of a reservoir whenever there is a rainfall to let out of his reservoir whatever has fallen on it. Nevertheless I think the precipitation belongs to the river, and not to the reservoir. If a man should start a farm by a riverside and irrigate from the rainfall to raise his crops, I do not think that other farmers who irrigate from the river to raise their crops would be entitled to an injunction against him. I think there is a difference in principle between the two things. There are laws for the purpose of regulating the storable amounts in reservoirs, while there is no such law and no practical way to cover such a condition as you suggest regarding farmers. I should have to look up the question as to what law I refer to relating to reservoirs which covers this question. I have never known any regulating power in this state to regulate a reservoir in respect to the precipitation which must fall upon its surface. But I think it is the general practice of engineers to treat the matter as I have treated it. It is my regular practice.

"Q. Do you know of any other engineer who follows that practice?"

(Objected to. Objection sustained. Exception.)

760 I cannot say that I know of any reservoir, either on the plains or in a stream bed, where in my practive I have treated the evaporation and precipitation in the way that I have treated them here. In some cases I have considered it immaterial. Wherever I have considered it material, I think I have dealt with it as I have here, but I cannot be positive as to that. I do not know of any case in the administration of the water laws of this state where a reservoir, either in a stream bed or apart from a stream bed, has been required to account to the stream for the precipitation.

If in my direct examination I referred to losses through the gates as being properly chargeable against the storage, I am not of the opinion that losses through the gates should not have been charged up against the reservoir.

The precipitation upon Lake Cheesman when the reservoir is full amounts to from 1,000 to 1,200 acre feet per annum.

I have concluded that the best draft to adopt for Lake Cheesman, under my assumption of available storage, is a draft of 40,000 acre feet, to which I apply a unit price of $35 per second foot, making a total value of Lake Cheesman as an entity of $1,400,000. On the other hand, if you should assume an annual draft of 50,000 acre feet, I would apply a price of $28 per acre foot, again making to total value $1,400,000. The factors entering into a determination of the value, or what the water is worth to a farmer for irrigation purposes; the stability of the water; the distance of the land that would be irrigated from the headgate of the canal; the length of time that it would probably take to dispose of this water; the overhead charges to the company—that is, the cost of administration until the sales were made, etc.; the cost of finding consumers, peddling out the water, etc.; perhaps other factors. Therefore the figure which I mention here is the figure which I have arrived at as the probable net amount of money realized by the reservoir out of the sale of each acre foot. It is not the price which the purchaser would pay. On the basis of a 40,000 acre foot draft, I think a purchaser would probably pay four or five dollars more per acre foot, that is about $40.

Out of the Standley Lake system, which is a new system and is a combination of direct flow and reservoir rights, they have been selling water at the rate of $50 per acre foot. I do not think the Standley Lake system, when its capacity is sold, will have any such efficiency as I have shown for Lake Cheesman on a 40,000 acre foot draft. I have given to Lake Cheesman lower prices because its water rights would not carry with them any interest in any distribution system. If I were estimating Lake Cheesman as a

761 means of furnishing a supplemental supply, instead of a sole supply, I would place different unit values upon the water rights, but it is my opinion that it would be practically impossible to find a market for all the Cheesman and Marston lake waters as supplemental supply, nor for the water of Lake Cheesman by itself, if we assume that all of these waters claimed by The Denver Union Water Company are to be turned to irrigation purposes. If a market existed for Lake Cheesman's water as a supplemental supply, I

would add to my unit price $5 per acre foot, making a total of $45. I am a bear on water right values. I do not agree even with Mr. Field upon that subject. I do not think there is a sufficient demand for supplemental supply in ditches now existing and not having an adequate supply to consume even as much as 40,000 acre feet per annum at $40 per acre foot.

In the New York Trust Company case, already quoted from, I testified in substance (exact quotation in original transcript) that the value of an acre foot of water varies, with the priority, etc., from $25 to $50, and that the value of an acre foot of water usually depends upon the source from which it is obtained; as, for example, an acre foot of water from Barr Lake would be worth considerably more than an acre foot from Standley lake or Milton lake. Standley lake and Milton lake are the lakes of the Denver Reservoir Irrigation Company, or Standley Lake System. Barr Lake is the lake having a priority of 11,000 acre feet, prior to that of Cheesman, located in District No. 2, and fed by the Burlington ditch. The reason for that statement is because of the greater reliability of the supply from Barr lake, and I think I must have had in mind the assumption that all the rights of each were to be sold.

I also testified in the New York Trust Company case in substance (exact quotation in original transcript) that the Standley Lake system was selling water at $50 an acre foot, although at that time they had not yet secured any water, although I believe they had some water in the resrvoir. I think the rights in Standley Lake and the system which goes with it are probably worth more than Cheesman Lake water.

When I said that water was worth from $25 to $50 per acre foot I undoubtedly took into consideration the sale price. My estimates of value in this case are based on practical application and what I think the farmer can afford to pay, and also what the practice is among farmers as to the purchase of water. I do not think $50 per acre foot is more than the farmer can afford to pay, if the right carries with it the right to convey the water to his lands. The sale of Cheesman water does not include any method of taking the water to the land. I think the cost of that would be $15 per
762 acre foot right. That cost depends altogether upon the distance from the intake of the ditch to the point where the lands are located. I have not investigated the charges made by existing ditches for conveying water. I have discounted the price which I would otherwise place upon Lake Cheesman water, used as a sole supply, because of the overhead cost and charges which would be involved in marketing the water, etc. I have not made exact estimates of those costs. I have known of cases under various systems where the cost of selling the water has run from $1 up to $10 per acre of land. On a duty of 2 acre feet per acre, that would mean from 50 cents to $5 per acre foot. In the case of Lake Cheesman I expect the cost would be somewhere in the neighborhood of $5 per acre foot.

There is a great cry and a great need for irrigation water in the vicinity of Denver. There are thousands of acres in the vicinity

of Denver which are unirrigated and untilled, because of lack of water, not obtainable under present conditions.

I once managed an irrigation project whose business it was to sell water rights. That was many years ago, in the Montezuma valley, which is a long ways from Denver. There is a difference between conditions in the Montezuma valley at that time and those existing in Denver today. The Montezuma enterprise failed two two or three times. I went down with the first receiver in 1887. It failed again about 1890. That is the only irrigation enterprise with which I have been connected in an executive and managerial capacity.

$40 per acre foot is what I would pay for the water if I were a farmer. I believe I could buy Lake Cheesman water at $35 per acre foot, if that water was to be thrown on the market. I believe I can buy Antero water for $30, but they reserve the right to sell the entire capacity of the reservoir, and Antero under those conditions would be less efficient than Lake Cheesman.

I do not believe I can specify any instance where under similar conditions you could get a like water right to that of Lake Cheesman for any such price as $35 per acre foot, that is as storage water; but I could go under ditches that furnish as good a supply as Lake Cheesman and get irrigated land at prices that would approximate the same amount; land as good as that around Denver, and in the irrigated valleys around Greeley, Boulder, Longmont and Loveland, under the older ditches, such as the Brantner, the Lupton, etc. It happens that in the vicinity of Denver there is as much lack of water as there is in the vicinity of any large town in the state.

I know of the Pleasant Valley district near Greeley, and have heard that Bruce Eaton, son of Governor Eaton, and one of
763 the largest landowners in Colorado, has in the last few years bought hundreds, and perhaps thousands, of acres in that district and paid therefor exceeding $200 or $250 an acre, but that purchase carried with it water rights, improvements, etc. Those prices are no measure of the value of the water alone, and it is upon that assumption that I have come to my conclusion as to the value of Lake Cheesman water.

Have been a partner of Mr. Field's for a long time, and was associated and participated with him in the preparation of the reports filed with the old board of appraisers. I did not participate in the preparation of the Bates report, but have read it over since its preparation. Have never compared my opinions or conclusions with those expressed by Mr. Field in the Bates report.

(Attention of witness is called to statement in the Bates report as follows: "It is conceded at the onset that the demand for water is in excess of any possible development, and that the sale of water can be made, with little or no expense, to the full amount of the supply, at the present values of such water privileges, that the development of any or all of these reservoirs will in no wise depress the present prices." Objected to. Objection sustained. Exception.)

I participated in the recent report made to the Public Utilities

Commission by its committee of engineers. I was chairman of that board of engineers. That report, at page 217, states: "In this connection, especial attention was also given to the following obvious facts: * * * 2. The uncultivated and even unoccupied condition of vast tracts under canals near Denver, this condition being due solely to an insufficient supply of water. 3. The undeveloped portions of the Henrylyn, Denver-Greeley, East Denver and other irrigation districts in this locality, which will require increasingly more water for many years, if it is in any way available * * * 5. The obvious need of more water for irrigation in the vicinity of Denver, rather than less." I subscribed to those statements. Nevertheless it is my opinion that the cost of marketing Lake Cheesman water will be approximately $5 per acre foot.

The difference between the operation of the reservoir on the 40,000 and the 50,000 acre foot draft, which causes a difference in price per acre foot of $7, is: (1) with decreased efficiency the value would be less; (2) with more acre feet to be sold the time required for disposing of the water would probably be greater, and the overhead charges consequently greater. On the 50,000 acre foot draft the water might be sold at a gross price of $32.50 or $33 per acre foot. I am inclined to think that the difference per acre foot between that and the 40,000 acre foot draft would be
764 $7 or $8. I am inclined to think there would be that much difference in actual return to the company at least. My estimate is based entirely upon the value to the company. As between the gross selling price per acre foot, that difference might be a little high, but I think it will approximate that. My judgment upon that point is not based upon any actual knowledge of differences in price created by differences in efficiency. I have no knowledge of any parallel cases. I have not myself had sufficient experience in marketing water rights from reservoirs to know what difference in selling price is brought about by a given difference in efficiency.

Exhibit A-67 is a transcript of the tables relating to Lake Cheesman employed in the report filed by Mr. Field and myself with the former board of appraisers. I have made no comparison of the estimates of canal demands stated in Exhibit A-67 with those shown in this case in my Exhibit 44, page 12.

My estimates of the total available storage in the years 1900 to 1904 as shown by Exhibit A-67 differ materially from my estimates of the total storage now made, as shown by Exhibit 44. The basis is entirely different. My determination in 1908 was not necessarily wrong. I would not say that my present estimate is necessarily incorrect. All these matters are estimates. I think it is true of every estimate that has been made that there is a considerable margin of error, or possible error, which must be taken into consideration, both in the basis, the method and the application of the method. I believe that on the average my estimate would be found to be most nearly right. I think the basis used by me is upon the average more accurate than any of the other bases. The basis which I have taken is, as already stated, the year 1913.

In our report to the former board of appraisers, and upon consideration of tables A-67, based upon an assumed draft of 45,000 acre feet, we concluded that the reservoir would not stand an annual draft greater than 40,000 acre feet. In that connection we stated in our report: "We find that there is an aggregate deficiency in the five years of about 40,000 acre feet, or 8,000 acre feet per year. We are justified in taking a certain amount of risk of shortage, and in occasionally asking the farmer to do with a little less than the average amount. Assuming that the justifiable deficiency is 3,000 acre feet per annum, we have left 8,000, less 3,000, or 5,000 acre feet of deficiency which is justified, and deducting this from the average assumed, 45,000 acre feet, we find that the maximum average which we are justified in selling is 40,000 acre feet per annum." I have not applied any such consideration as that in the present case.

765 As shown by Exhibit 44, on the 40,000 acre foot draft the annual deficiency would be about 1,700 acre feet. That is much less than the 3,000 acre feet which I said I was justifiable in my former estimate. Taking in 1899 and 1914, making a total period of 16 years, the average annual deficiency would be only about 1,500 acre feet, which is just about one-half the deficiency which in 1908, in advising the board of appraisers, I said was justifiable in making sales to the farmers. That does not necessarily indicate that the reservoir under my present estimate ought to be operated upon a larger annual draft than 40,000 acre feet. Upon my present estimate, as shown by Exhibit 44, even if we operated upon the 50,000 acre foot draft, the result in the period of 16 years mentioned would be an average annual deficiency of a little over 3,000 acre feet. Nevertheless, from my present point of view I would not be justified in adopting the 50,000 acre foot draft. I have changed my point of view to some extent. I think I am a little more conservative than I was in 1908; I think all engineers are.

In 1908 we applied a unit price of $40 per acre foot to the entire 40,000 acre feet, but in our supplemental report of January 20, 1908, we applied to an average available capacity of 35,000 acre feet a unit price of $30 per acre foot, stating: "This valuation per acre foot results from deducting $10 per acre foot for the purchase and construction of transportation facilities for the delivery of the water."

In the present case, in assigning values to Lake Cheesman, I have taken into consideration what the farmer would have to pay for the construction of canals for the delivery of the water.

In our report to the appraisers in December, 1907, we valued Lake Cheesman, as an entity, at $1,600,000, upon an assumed draft of 40,000 acre feet at $40 per acre foot. Even at that value we stated: "It may seem surprising that this famous reservoir's value for irrigation purposes is not in excess of its cost."

In a later report, dated January 20, 1908, we reduced total value of Cheesman to $1,050,000, an average available capacity of 35,000 acre feet at $30 per acre foot, as stated above. Mr. Field swore to both reports. I have now gone back to the average yield because the average stream flow is now found to be more than we then thought

it was. I have not changed the unit price because of the granting of the decree and seven years of actual use.

I became a member of the Public Utilities Commission in June, 1910. Between that date and September 10th I proceeded to make a preliminary estimate of the cost to the city of building a new water plant. That estimate included the acquisition of the Bates
766 or Highline reservoir. I had before me at that time Mr. Filed's report Exhibit A-66, upon the Bates or Highline reservoir. I used that reservoir as a basis in making the estimate.

In my report to the former board of appraisers in 1907 I stated: "It has been shown in the discussion of Lake Cheesman's rights that little, if any, water is available in the south fork after 40,000 acre feet per year have been furnished from that reservoir; hence in further discussion of storage possibilities on the South Platte river only storage sites which derive their supply from the north fork will be considered. * * * Upon an investigation of the records of the discharge of the South Platte at Deansbury it is seen that there is available for storage purposes, after all demands of prior rights in districts 2 and 8 have been satisfied, an average amount of approximately 16,000 acre feet per annum." In our later report of January 20, 1908, we were obliged to reduce even that draft upon Lake Cheesman, because of reduction of the available storage for Lake Cheesman which we had found.

In January, 1912, I testified in the case of the New York Trust Company against the City and County of Denver. In that testimony I dealt with the estimate of $7,000,000 for the construction of a new city plant, and described the Bates reservoir as the one proposed for the purposes of that estimate. In that testimony I stated in substance (exact quotation in original transcript) that for the purpose of making that estimate we used the Bates reservoir site on the south fork of the South Platte, and that "Mr. Field of my firm had recently made a report—a preliminary report upon that reservoir site, and I took his figures." The report of Mr. Field referred to is Exhibit A-66. I presume I knew of that report on the Bates reservoir shortly after it was written. In the summer of 1910, for the purpose of estimating the cost of a new plant for Denver, I adopted and made use of Mr. Field's conclusions regarding the Bates reservoir. In my testimony in the New York Trust Company case, given in January, 1912, speaking of what I did in the summer of 1910, I said that the storage reservoir contemplated in connection with his estimate of the cost of a new city plant was the Bates reservoir, with a capacity of 107,000 acre feet.

In my testimony in the New York Trust Company case, in January, 1912, I said in substance, speaking of this Bates reservoir, that it contemplated securing a portion of its supply from the North fork; "I think an average flow of about 30 cubic feet per second of time;" that a conservative estimate of the supply from the north fork would be an average of 30 cubic feet per second; that the feeder canal would have a carrying capacity of 300 second feet, and
767 that I would hope to secure from the north fork an average supply of 30 second feet, "and I believe a great deal more."

An average supply from the north fork of 30 second feet would produce in a year about 22,000 acre feet. The difference between that and the 15,000 acre feet stated in the report to the former appraisers as the limit of the north fork supply is not so very great. The estimates were conservative, and naturally I hoped to secure more, as we always do when we make a conservative estimate.

In my testimony in the New York Trust Company case I also stated that this Bates reservoir, in order to be filled with water, would not at all need the supply from the North fork. I then testified in substance (exact quotation in original transcript) that personally I had never thought it essential to construct the feeder ditch from the North fork; that such feeder ditch was not at all necessary to the success of our plan, and that according to my ideas we could really have our water supply depend solely upon the waters flowing in the south fork of the South Platte river.

In my testimony in the New York Trust Company case I also said in substance (exact quotation in original transcript) that the principal source of supply for the reservoir would be from the south fork of the South Platte river, upon which the reservoir is located, and that I thought the south fork would furnish an adequate supply for that reservoir, in connection with the diversion from the north fork; that for that purpose I expected to get from the south fork of the South Platte 40 or 50 cubic feet per second, and that I thought that was available. Notwithstanding that testimony, I am inclined now to doubt whether there is that quantity available for such a reservoir in the south fork of the South Platte, subsequent in point of time to Cheesman and Antero.

I do not know what occurred between the time I reported to the former board of appraisers in 1908 and the time I was estimating the cost of a city plant in 1910 to cause me to change my mind about the supply of water available for storage in the south fork of the South Platte.

As to what has occurred since 1910, when I made that estimate, and since January, 1912, when I testified in the New York Trust Company case, which has again caused me to change my mind about the available storage water in the south fork, "six years have occurred since 1908, four years since 1910 and two years since 1912."

40 or 50 second feet would furnish in the course of a year over 36,000 acre feet. In 1910 and in 1912 it was my opinion that a reservoir, such as the Bates reservoir, and at its location in
768 the south fork of the South Platte, subsequent in point of time to Cheesman and Antero, and subsequent to numerous other reservoirs which have intervening priorities after Cheesman, would be enabled, nevertheless, to get on the average each year 36,000 acre feet from the south fork of the South Platte. I doubt now if there would be as much surplus as that. I have modified my opinion to some extent.

In my testimony in the New York Trust Company case, in January, 1912, I stated in substance (exact quotation in original transcript) that for the reservoir I expected to get at least 40 cubic feet per second from the south fork of the South Platte and that that was

independent of the water rights of The Denver Union Water Company and regardless of and over and above their storage rights for Lake Cheesman.

The Bates reservoir, concerning which those statements were made as to the opportunity of getting such a supply of storage from the south fork of the South Platte, would be subsequent in point of time not only to Lake Cheesman, but also to the Antero, and to the storage rights of numerous other reservoirs which have been built since Cheesman was constructed.

Exhibit 44, page 38, considers certain of the water rights by groups. Group A includes the Platte Canon ditch, and also rights at or near the mouth of Platte Canon. I have estimated the yield of those rights according to the diversions actually made by the Denver Union Water Company at those points in the year 1913. I have estimated that the yield, measured by the diversions, for the months of January, February, March, April, November and December would be stored in Marston Lake, and valued it at $30 per acre foot. I have estimated a less unit price on this and on Cheesman water than on the yield by the Bear Creek and Turkey Creek rights, because: (1) the right would have to be changed to storage rights and a decree obtained; (2) the water is diverted by a wood-stave conduit; (3) the water could not be used directly on lands under the High-line ditch; (4) the loss in transportation on this water would probably be greater; (5) some of the water is obtained rather from the late claims of the company than from the decreed rights of the Platte Canon ditch. I considered that the water stored in Marston Lake from the Platte Canon supply would have to be transported to some other location. Marston Lake is located in the immediate vicinity of the lake in which I proposed to store the water yielded by the Bear Creek and Turkey Creek rights.

The cost of maintenance of a wooden conduit will be greater than the cost of maintenance of an irrigation ditch. One reason I made the reduction in price is because I believe the works now employed
for the development and diversion of that water are not
769 really the proper kind of works for irrigation uses.

Although I have first reduced my unit price because that conduit is used to divert the water, nevertheless I think it fair in finding the net value of the water to deduct the gross reproduction cost of the conduit.

As to the summer flow of the rights listed in group A, I have measured the yield by the actual diversions made by the Water Company in the month of May, 1913, as shown by table 13, page 11, Exhibit 44, to which, after deducting what I considered necessary for the Lehow, Hugens and Shellabarger claims, I have applied a unit price of $2,000 per second foot. That is equivalent to $5.43 per acre foot for the yield of those rights, according to my estimate of the flow during the irrigation season. That might be a very low valuation if you had provision for storage and means of delivering it to the land, etc. I have estimated the yield of the Bear Creek and Turkey Creek rights, stored in the water company's reservoirs, at $35 per acre foot. I think the difference betwen $35 per acre foot

and $5.43 per acre foot fairly represents the difference in value between direct flow rights and storage rights, under the conditions there existing. Water which is furnished in May and June, and possibly to some extent in July, is worth less than water which is stored and can be used later in the season. Water delivered during the months of April, May, June and July, practically as a direct flow, is worth less than stored water which may be delivered later in the season. I have estimated the value of the reservoir supplies of The Denver Union Water Company as sole supplies, and not as supplemental supplies.

As direct flow rights, the Platte Canon Ditch rights, taken by themselves and sold as irrigation rights, might be worth a little more than $2,000 per second foot. Real estate men have told me that they could get such water at prices not exceeding $2,000 per second foot. I remember I was told that I could get such rights in the Nevada ditch and in the Brown ditch. "Q. Who told you that you could get such rights in the Nevada ditch at $2,000 per foot?" (Objected to. Objection sustained. Exception.) The best offer, and practically the only offer, I ever had of rights in the Nevada ditch was made by a Mr. Malone. Malone's offer covered the following rights in the Nevada ditch: priority of August 30, 1861, 7.54 second feet in the Nevada ditch; priority of November 30, 1865, 9.24 second feet in the Last Chance ditch; priority of March 3, 1868, 12.07 second feet, making a total of 28.85 second feet. Those priorities are almost entirely subsequent in point of time to the priorities of the Platte Canon ditch. I testified in the New York Trust
770 Company case about the Malone offer as follows: "The offer was made on the basis of $5,000 per cubic foot per second." If I made that statement I was probably correct at that time, and I am not correct now.

In arriving at my conclusions as to value, I have taken into consideration that some of these rights have not existing decrees, or that there is some necessity of change of use from domestic to irrigation use, and that there are other like matters requiring adjudication. I do not know how much additionad value I would estimate if decrees for irrigation purposes actually existed. I have taken into consideration a number of things of that sort, which have caused me to reduce the values on these rights, among others the following: that while the Platte Canon ditch has diverted to its full capacity, the water has not been used to a great extent for irrigation purposes for many years, and I cannot say whether the water so diverted was that to which the ditch was entitled; I have taken into consideration the necessity of changing the use from domestic to irrigation use in respect to some of these rights; the necessity of getting a decree for these rights, and other things of like character. If the water company actually had decrees entitling it to make diversions for irrigation purposes at the rates at which it has in the past actually diverted water for other purposes, I might assign higher values. I have no means of knowing what sort of decrees would be given. Because of the existence of these considerations I have assigned less values than I otherwise would.

Exhibit 44, page 38, items 5 and 6: the original diversion of item 5 was 1870, and of item 6 1878. These are early diversions. Even that of 1878 antedates the Highline Ditch, and since the intake is situated further down the stream, these rights have the advantage, which the Highline does not have, of the accretions to the stream and seepage coming in in District 8. In assigning my value here I have in mind that there are no decrees for these old rights, and particularly that they are not decreed as irrigation rights. Therefore I have assigned a value to the second foot rights of the Highline of $1,250, and to items 5 and 6 a value of $100 per second foot of the actual delivery in 1910, although the Highline is later in point of time and so situated that it cannot receive the seepage and inflow.

In my report to the former board of appraisers I valued item 5 at $1,200 per second foot for 2.05 second feet, in the original report, but marked it "Questionable—Abandoned." In that report I valued item 6 at $1,000 per second foot for 30 second feet, but marked it "Questionable." The total was deducted from our former valuation.

771 As to item 7, Cherry Creek right, we valued that in 1908 at $1,000 per second foot for 10 second feet, making a total of $10,000, but marked it as "Questionable." However, in our later report of January 20, 1908, we eliminated the word "Questionable" and gave to the Cherry Creek rights a nominal value of $100 per second foot for 10 second feet.

I have taken as the basis for the valuations which I have assigned to all of the water rights in the present case what I deemed to be the irrigation values. The values which I have assigned here have in no sense exceeded what I deemed to be the value of the rights for irrigation purposes. Moreover, I have in the main assumed, for the purpose of applying this irrigation value, that there must have occurred an actual change in the status, so that the rights, instead of being used as a supply for the city of Denver and its inhabitants, as they are now used, will be placed in such a situation that they can be and will be and are being used as a supply for irrigation purposes. I made that assumption in practically every case. In that connection I took into consideration the difficulties, the loss, the expense and the overhead charges, and other like matters, which I assumed would be involved in bringing about such a change of status. In other words, my estimates of value represent what in my judgment the Water Company would obtain net if it were obliged to so change the status and to dispose of the rights for irrigation purposes. Moreover, I also took into consideration the effect upon the market for irrigation water rights of suddenly placing upon the market such a large body of rights as are here represented. I think the values which I have assigned to the water rights are analogous to what engineers term junk value or scrap value. It might under some conditions be possible that, with a change in the character of the use, their value would amount to more than their value for the purpose for which they are being used; but I am not undertaking to say that the value which I have here assigned to the water rights for irriga-

tion purposes exceeds the value of such rights for the use to which they are now devoted.

After having arrived at these values by the method described, it is my theory that there ought to be some deduction therefrom on account of the structures to arrive at what I would designate the net value of the water rights. I think that deduction in each instance ought to be the gross reproduction cost of the structure, without taking out depreciation. The structures which I think ought to be deducted are those which are necessary to provide and furnish the water right for irrigation purposes—not necessarily the structures that are now used for delivering water to the city of
772 Denver as a domestic supply. It is generally true that for irrigation purposes water rights are developed and made useful by means of structures which are less expensive than the structures which are required to develop and make useful the same water rights for domestic or city purposes. I think the structures to be deducted should be the structures as they exist, so far as those structures are necessary to develop the water and make the water useful. Starting at the point at which the water becomes available, the structures might properly be changed to the character of structures usually used for irrigation purposes.

It may be true that upon these assumptions the value which I have assigned to the total entity is in a number of cases less than the reproduction cost of the structures to be deducted. Viewed in that light, some of these water rights are worse than valueless; they are worth less than nothing for irrigation purposes. But in that regard, I confine my judgment to the value of the water for irrigation purposes. That is the only consideration which I have given to the matter. I certainly do not think that these water rights are worth less than nothing when viewed as water rights used and useful as they are today for the purpose of supplying the city and county of Denver and its inhabitants with water. Some of these water rights may be worth more for the purpose to which they are now devoted than for irrigation uses, and some may not.

In my report to the former board of appraisers dated December, 1907, I stated: "It may be argued that water for domestic and municipal purposes has a higher value than obtains for agricultural uses, and this is true." It is undoubtedly true that water used for the domestic supply of a city is applied to a higher and more valuable use than irrigation, and will stand, if necessary, a higher cost. In other words, to make my meaning plain, my opinion is that water for domestic purposes is worth what it costs to get the water. It might be a very much greater cost than the ordinary irrigation cost. I am not questioning that the value of the water from the various sources of supply is what it cost to produce for domestic purposes. In my opinion that value would be limited to the amounts properly chargeable against the structures, including in that amount cost that may have been entered into in purchasing water rights. I call that a part of the cost of construction. If the cost of acquiring the water rights has been paid for by the consumers out of rates, no addition should be made for the water rights.

My theory amounts practically to this: that the water company is in no event entitled to a return upon the actual present value of the water rights, but only upon the cost thereof, and that
773 it is not entitled to a return even upon the cost if it has received that back in rates previously charged. The theory is that what a utility is entitled to have a return upon is the actual cost to it of the property which is devoted to the public service. I believe that to be the case. In my judgment the value of these water rights for the purpose of rate making ought to be the cost which would be incurred in acquiring them, if that entered into the construction cost.

I am of the opinion that the more nearly you can approach original cost the better the basis, and that the only excuse for using present day cost is the absence of information as to the original cost. I have given some consideration to what it would cost at the present day to reproduce these water rights, or to produce rights of the same efficiency for the supplying of the city and its inhabitants. The supply of the South Platte river and its tributaries is overappropriated.

If at the present time some one undertook to construct a water works plant to supply Denver and its inhabitants, he would, in addition to constructing the physical component parts of that plant, have to acquire water rights. If he got them from the South Platte river or its tributaries he would have to obtain them to a considerable extent by condemnation or purchase. Unless he purchased or condemned the rights of the water company, which are now devoted to the domestic supply, he would have to purchase or condemn rights which are now devoted to agricultural and irrigation purposes. He would have to pay for them at irrigation prices. Unless he bought only a portion of the supply of each irrigation enterprise, he would have to pay not only for the water rights, but also for the structures which he put out of commission. He would probably also have to pay in addition damages on account of the lands which he had thus deprived of their water supply. After that he would have to go through the legal process of changing the use from irrigation to domestic, the time of diversion from the irrigation season to all the year round, and the point of diversion to such point as would make them available for use in Denver. All of these things would involve expense, losses of quantity of water obtainable at the changed point of diversion, possible collision with other rights, especially in the change from direct irrigation use to storage or all the year round use. That would occur to some extent; I do not know to what. That proposition is beset with some legal questions about which I do not feel qualified to express a definite opinion. It is in general true that all of these things would cost the man providing a new water system for Denver not only the original irrigation price or value of the rights, but all of these other matters of expense
774 and overhead cost. Moreover, it would undoubtedly cost time and money to assemble these rights. The money which had been invested from time to time would be dead capital until such time as all of the property had been assembled, the plant completed

and put into actual earning shape. Then in addition to having purchased water rights at irrigation rates, and in addition to having incurred all the additional expenditures mentioned above in respect thereto, such a man would have to construct his water works structures.

It follows that, viewed as a present day cost, and measuring value by that, the value of the water works structures and the water rights, considered as an entity, is the sum of the reproduction cost of the water works structures, plus the irrigation cost of the water rights, plus all of these other overhead expenses, interest during construction and other like expenses referred to above in connection with the water rights.

If I were making an estimate on the cost of water for domestic purposes and for use in the city, I should be working upon an entirely different basis from the basis outlined to arrive at the conclusions here announced as to the value of these water rights for irrigation purposes, concerning which I have been testifying, and I would have treated it in a different way.

The only thing which the Public Utilities Commission is now authorized or required to do is the building of a new plant and the providing of a new water supply for Denver and its inhabitants, wholly independent of the plant of The Denver Union Water Company. From that point of view, it is a potential possibility that the city, acting through myself as public utilities commissioner, will be a purchaser, or is a prospective purchaser of water rights. I am therefore, on behalf of the city, a potential or possible purchaser of water rights. As public utilities commissioner, it is my duty, and it is to the interest of the city, to obtain such water rights at the lowest possible price.

Redirect examination:

Although it has been my experience and observation that water commissioners' reports are not always entirely accurate, nevertheless I have used them in making up my computations and determinations in this case, because the water commissioners are state officers, regularly appointed, and charged with the duty of distributing the water and of compiling data, and I know of no other records than their reports which are more accurate, or which are even sufficient to be utilized in such an investigation as this.

775 The work of my assistants in this case was done under my direction and general supervision. The general scheme was outlined by me. The principal assistant was W. L. Reynolds.

The Highline Ditch has a decree for 1184 second feet and a capacity of about 600 second feet. So far as my knowledge goes there have been no additional acres brought under cultivation solely by virtue of the Antero additional rights. My knowledge regarding the acreage under that ditch is derived from the official reports of the water commissioner and from statements made to me by officers of the ditch.

It is my understanding that the amounts returned to the river from the ditches through their waste ways are intended to be in-

cluded by the commissioners in the amount credited to accretion, return flow, seepage, etc. If there is an accretion by virtue of such return flow, it would appear in the stream flow discharged from the district. It is my opinion that the loss caused by conveying such water through a canal would be less than the loss in the stream bed, particularly at low stages of the stream.

In general practice, so far as water commissioners' reports are concerned, and also in engineers' estimates on irrigation enterprises, duty of water is determined by measuring the diversion at the headgate. To determine the quantity actually applied to the land deduction must be made for loss in transit. This will vary in different localities, in different ditches, and in different amounts of water.

In determining whether the quantity diverted at the headgate of a ditch represents a wasteful or unnecessarily large diversion, one must consider the character of the soil, the character of the crops, the size of the lots to be irrigated and the distance to which the water is to be conveyed, as well as the character of the ditch and the means provided for the quick return to the river of any excess diversion.

Exhibit 44, page 9, table 11; the diversions of the Burlington ditch were used in my computations and determinations, particularly for the months May to October inclusive.

Because of the change in the Fort Morgan Land and Reservoir Company's ditch decree, we must take into consideration the additional quantity specified in that decree as a demand of District No. 1 upon District No. 2.

The Union ditch is used for conveying water to the Lower Latham reservoir, also for direct irrigation. I have looked into the records to see whether they contained any statements of diversions of this ditch in the summer months for storage purposes, but found no record of any such supply. The same is true as to the Evans No. 2 ditch.

776 Exhibit 44, table 7, page 6, was not used for the months of January, February, March, April, November and December in arriving at my conclusions as to demand upon the river.

Exhibit 44, page 3, table 4: discharge of the South Platte in April 1905 was obtained by expanding actual record of flow for 25 days to 30 days, yielding 33,500 acre feet, to which was added 15,147 acre feet understood to have been stored in Lake Cheesman, making a total of 48,647 acre feet.

In my investigation of 1910 relative to the use of the Bates reservoir for city supply, I had in mind the possible utilization of the flood flows, surplus water, and the possible purchase of water rights to be stored, and the possible transfer of portions of the rights belonging to the city for storage at that point, and the possibility that the claims of The Denver Union Water Company might not be supported by decisions of the courts.

In 1908 the basis of my estimate was irrigation value only, and the rights were considered as claimed by the water company, some allowance being made based on our opinion of the amount that could be obtained from those claims.

In making my present determination I have considered the

claimed rights of the water company, the basis taken being the amount of water used by the company in 1913, and the estimate of value being for irrigation purposes only.

The most natural place to use the yield of item 7, Cherry Creek right, for irrigation purposes is on lands in that locality. If the yield of that right was carried in a ditch by itself for a considerable distance, it is presumable that a very large portion of the water would be lost.

The offer which I testified about of 28 and a fraction second feet of Nevada and Last Chance ditch rights at a price of $5,000 per second foot, was at a gross price for land, water and improvements. All of these things entered into the amount of $5,000 per second foot.

Recross-examination:

As to the offer made by Malone to sell Nevada and Last Chance ditch rights, I do not remember whether I testified in the New York Trust Company case that that was a proposition to sell water rights alone at $5,000 a second foot, but I believe the fact is as I have now stated it. In the New York Trust Company case I testified in reference to said transaction in substance as follows (exact quotation in original transcript): "that the price made upon the water right was independent of the price of the land; the offer made to Mr. Malone was for both land and water;" that the offer at the rate of $5,000 per cubic foot per second for the water alone was an oral offer, made by Mr. Malone to me individually. My former testimony plainly says that the offer was at the rate of $5,000 per cubic foot
777 per second for the water alone. I stated in my former testimony in the New York Trust Company case that the offer made by the owner to Mr. Malone covered both the land and the water, but that the offer made by Mr. Malone to me covered the water only, and was at the rate of $5,000 a second foot. Now that my recollection has been refreshed, I do not remember whether or not that is the way it occurred.

As to my examination of the Bates reservoir in 1910, and my testimony on redirect examination relating thereto: when I spoke of the utilization of the flood flows I meant to impound in that reservoir any unappropriated water that might flow in the south fork of the South Platte and through the feeder ditch. When in my testimony in the New York Trust Company case I referred to flood flows or flows directly from the river, I presume what I had in mind was such unappropriated water. At that time I had before me Mr. Field's Bates report, Exhibit A-66. Undoubtedly I took into consideration his estimates there made as to available storage and accepted them as an opinion to be considered in connection with other information.

When in my redirect examination I referred, in this connection, to the possibility that the claims of The Denver Union Water Company might not be supported, I meant that there might be some question about the right of The Denver Union Water Company to convert Lake Cheesman from a domestic to an irrigation reservoir. I do not know whether or not I had that matter in mind when I was

giving my testimony in the New York Trust Company case. I believe I testified at that time that my estimate of storage in the Bates reservoir was over and above and independent of any such consideration. I then testified in substance (exact quotation in original transcript) that I expected to derive 40 cubic feet per second from the south fork of the South Platte, independent of the water rights of the water company, and over and above their storage rights for Lake Cheesman. I still believe it would be possible to secure as much as 40 cubic feet per second without acquiring any of the water company's rights. In making that estimate I eliminated from consideration the matters mentioned on redirect examination.

Exhibit 44, page 3, table 4: In figuring up available storage for Cheesman as influenced by the flow of the South Platte river, as shown by this table, I took the figures shown for the individual months whether the same were followed by a star, a prime or two primes.

Exhibit 44, page 6, table 7: What I meant in redirect examination when I said that I made no use of what appears there respecting the months January to April, inclusive, and November and
778 december of each year, was that the inflow in those months was sufficiently large to offset all demands below, except the demands of the water company for its direct diversion.

Exhibit 44, page 9, table 11: When on redirect examination I said in respect to the Burlington ditch that I made no use in my computations of the diversions in the months of January, March, April, November and December, what I meant was that in those particular months the inflow afforded a quantity entirely sufficient to offset the demands for irrigation, so that the Burlington ditch diversions would not amount to a demand on the canon. But I did make use of the diversion of the Burlington in October, 1913, and that contributed to the demand on the canon as estimated by me.

When a ditch is running at its ordinary capacity, I think there is less loss in transit that when the water is carried in the river. I think it might often occur that the loss in transit by such ditch conveyance would be less than the loss in the South Platte river in Districts 8 and 2, particularly with a comparatively small flow in the stream.

As to the increase of acreage under the Highline, and whether it has been caused by additional water furnished or expected to be furnished from the Antero reservoir, I have made a computation showing the number of acres cultivated under said ditch, as reported by the water commissioner, in the years 1909 to 1913 inclusive, and find that there was a rather regular increase. I do not think the expectation of Antero water dated back to 1909; possibly to 1910. There has been no considerable increase in acreage since 1909, and the increase has been rather gradual. I have no personal knowledge regarding this matter acquired by personal examination. I have only these reports of the water commissioner, and information obtained from one of the officers of the company.

I have been very much pressed for time in preparing for my testimony in this case on the subject of water rights. Since this case began I have been constantly in attendance in court, day in and

day out. Between the time of my reports to the former board of appraisers and the present hearing I have been acquiring such information as I could bearing on water rights in the South Platte, but have not made any particular investigation (until I did so for the purposes of this case) as to the rights of The Denver Union Water Company. So far as my investigation in immediate connection with this case is concerned, it has all occurred since the case began and the taking of testimony started. To a large extent my time has been spent in sitting in the court room and listening to the testimony of the various witnesses. Owing to the necessity
779 of my being in daily attendance here, a large part of the work of gathering specific data, tabulating it, etc., for the purpose of this testimony and the preparation of Exhibit 44 has necessarily been confided by me to assistants, of whom the principal one was Mr. W. L. Reynolds.

I testified on redirect examination that I found nothing in the water commisioners' reports to indicate that the water diverted in the year 1913 by the Union and Evans No. 2 ditches was used for storage. It is also true that I found nothing in those reports to indicate that the water so diverted, or part of it, was not so used.

Redirect examination:

Exhibit 44, page 3, table 4—December, 1902: the exhibit is in error; the quantity should be 2,600 acre feet instead of 17,700. That correction would decrease the percentage of that year to approximately 39.

Exhibit 44, page 14—December, 1902: should be corrected accordingly. This would eliminate the available storage for that month and reduce the total available storage for that year to 12,081. This error is carried along somewhat: on page 20, table 16, the amount shown opposite the year 3 should be 12,081, instead of 12,942, and the average at the foot of the column 48575, instead of 48,636; on page 23, second half of page, 861 opposite the word December should be eliminated, reducing total at the foot of the column to 8,071, instead of 8,932. In that table also the elimination of 861 for December would reduce the amounts following that month in the column "Amount in Reservoir" accordingly, and increase the deficiency in August by 861. Similar corrections will have to be made in the tables relating to the 50,000 acre foot draft.

Exhibit 44, page 3, table 4: figures for May to October, inclusive, in 1902, arrived at by taking recorded stream flow and adding actual storages at Lake Cheesman.

Exhibit 44, page 9, table 11: using the diversion of the Burlington as stated in that table the duty of water in District No. 2 would be 3.41 acre feet per acre irrigated; under the assumption that the Burlington diverted under its own direct irrigation priority 22,000 acre feet, that duty would be 2.7 acre feet per acre. Combining this total duty with the duty in District 8 according to the actual diversions in the latter district, gives an average duty of 2.86 acre feet per acre. As to District No. 2, considering acres irrigable as reported by the water commissioner, instead of acres irrigated, an average

duty in District No. 2 results of 3.24 or 2.57 acre feet per
780 acre, depending upon whether we use the full diversion as made by the Burlington or only 22,000 acre feet thereof.

As to District No. 8, on the basis of irrigable lands, estimating the irrigable acres under the Highline ditch, exclusive of East Denver Municipal District, as 50,000 acres, I found that if all of the lands covered by the ditches in District 8 were to be irrigated with the amount of water diverted in 1913, the result would be 1.93 acre feet per acre. Combining Districts 8 and 2 upon the basis of irrigable acres instead of those actually irrigated, gives an average duty of 2.75 acre feet per acre upon the entire diversions for 1913, and 2.33 acre feet per acre using 22,000 acre feet as the diversion of the Burlington.

Recross-examination:

I did not look up to see what was claimed as the acreage in the East Denver district, but for the 90,000 acres stated in the water commissioner's report as the quantity irrigable from the Highline ditch I substituted 50,000 acres. I mean by that that that is the number of acres lying under the Highline canal proper, without its extension, and which could be irrigated if the canal could get water for that purpose. What I mean by irrigable acres is irrigable in a physical sense—that is, the acres which lie below the canal. That is purely a computation. I did not take into consideration the ability of the ditch itself to divert water, considering its priority and the quantity which the stream affords. I think it is true that the supply of the Highline ditch is so varying and uncertain that farmers cannot rely upon waters from the Highline sufficiently constant in supply to irrigate 50,000 acres. The statements in the water commissioners' reports as to irrigable acres are the estimates made by ditch riders in the employ of the ditch companies and by them stated to the water commissioners.

Exhibit 44, page 9, table 11: Total quantity shown as diverted by Burlington ditch in 1913, 85,000 acre feet. For the purpose of one of my computations I deducted from that 63,000 acre feet. That deduction was made on the theory that 63,000 acre feet had been diverted for purposes of storage on priorities later than Cheesman.

Exhibit 44, page 3, table 4: In determining the discharge of the South Platte river for months April to October, 1902, as recorded in that table, I have taken the stream flows as recorded in the State Engineer's office and added thereto the actual storages at Lake Cheesman on those months as the same appear upon Exhibit 31.

I have examined the hydrograph of actual storage in Lake Cheesman contained in Exhibit 37, prepared and produced by the
781 witness Bull. The quantities added in the various months of 1902 as storages at Lake Cheesman to produce the figures in my Exhibit 44, table 4, do not correspond with the actual storages in those months of that year as shown by Mr. Bull's exhibit. According to the latter exhibit, apparently no such amounts as I have added were actually stored in those months. The quantities which I took were those which appeared upon Exhibit 31, produced by Mr. Field

when he was on the stand. In that exhibit the year 1902 was the first year in chronological order. Whenever, according to exhibit 31, there appeared no figures in the column relating to the outflow from Lake Cheesman in the year 1902, I have assumed that all of the inflow therein recorded was actually stored in the lake. I have some doubt as to whether those are the actual facts as they occurred in 1902. I do not consider it very material anyway. If those amounts should not have been added for 1902, the amounts shown as the stream flow for that year in my Exhibit 44, table 4, would be materially less, and that would still further reduce the total discharge of the river in 1902, and further reduce the percentage of that year as a year of discharge, as also shown in said table 4.

Recalled. Lands and structures.

Direct examination:

I was one of the committee of engineers appointed by the Public Utilities Commission in 1913 to examine the matter of the property and properly values of the Denver Union Water Company, the other members being E. C. Van Diest and C. P. Allen. My work was rather of a general character, to assist in keeping things going; to go over the data as brought in, and to consult with the other members of the committee regarding that data and the compilation of the report; it was rather general in character, and there was no particular part of that I had charge of. Some parts of the narrative report I wrote. All matters involving judgment or policy were discussed by myself and the other members of the committee; the compilations were gone over and passed upon.

We were pressed for time; we were crowded so to get the report done, and the amount of money given us was so small, that we were unable even to have additions checked or proof read, or anything of that kind. The members of the commission were working under a great deal of strain and stress, averaging I should think something like fifteen or sixteen hours a day, in order to get the thing done, even in its present form. Since this suit has been on trial those figures have been rechecked and the calculations have been gone over
782 and remade by Mr. Van Diest personally. I have not rechecked them. That, however, was done at my request and with my full knowledge and consent.

The final figures as set forth in Exhibit 54-19 express my judgment as to values and amounts.

In our estimates we valued certain lands as lands with water rights. We attributed a present day value to the lands and the water with them. The valuation of well-irrigated lands varies from $125 to $150 per acre. Generally speaking, about $60 of that was the water value.

The total estimated corrected value appearing on sheet 6*a* of Exhibit 54 represents my judgment as to the value of the property individually as needed by the city, except there is a doubt in my mind as to the propriety of including paving over mains, and also a doubt as to including the ranch lands. The propriety of including or ex-

cluding those two items is dependent upon legal questions, which I do not feel like passing upon.

As to the items listed for deduction on said sheet 6*a* of Exhibit 54, those represent my conclusions as to proper deductions that should be made.

As to Exhibit 54-25, page 1: It is my judgment that all of the items there listed for deduction should be deducted, and also that the amount left included in the first item of water rights should also be deducted.

(Objected to as calling for legal conclusions. Objection overruled. Exception.)

Exhibit 23, sheet 4—items for deduction: in my opinion the items there listed are proper for exclusion in determining the present fair value of the property used and useful for water works purposes.

Exhibit 54-25, page 1, item 3; also page 2, schedule A; also further detailed schedules A-1, A-2 and A-3; it is my opinion that all of these items should be excluded.

Exhibit 55 is a tabulation prepared by me upon certain assumptions, stated in the exhibit, and showing deficits below or excesses above a fair earning upon those assumptions, as shown by the actual revenue of the Denver Union Water Company. (The table explained.)

The depreciation allowance has been deducted at the end of each year; net value each year has been ascertained by adding the net deficit or subtracting the net surplus, and then deducting the depreciation allowance, calculated at one per cent. This table was prepared for comparison with plaintiff's Exhibit A-19, table 2. This table is prepared simply for the purpose of showing what the
783 result would be in connection with that table if depreciation were deducted annually.

Exhibit 54-19, sheet 6-A, item Development Expense, $375,628: that was obtained by deducting the surpluses from the deficits in revenue in the table to which I have formerly referred, as contained in the engineers committee's report to the Public Utilities Commission.

As to interest during construction on lands, my recollection as to our method of determining that agrees with Mr. Van Diest's statement. Appreciation in the value of the lands entered into that discussion to some extent and was taken into consideration in arriving at our conclusions. As to interest during construction on items other than lands: I heard Mr. Van Diest's testimony, particularly that relating to Schedule G, the distribution system, also his testimony on that subject relating to other portions of the plant. My recollection as to the details is very hazy. "The matters I know were discussed, and I recollect that we used generally six per cent as a basis, and that some consideration was given to bank balances; but as to the particular details, I do not feel that my recollection is good enough to testify." My recollection is that we first applied interest during construction to Schedule G, distribution system, although I am not very clear as to that.

The descriptive matter in the report was prepared mostly a considerable time in advance of finishing the schedules.

Exhibit 55 offered as a mere computation and admitted. Exhibit 54 admitted.

Cross-examination.

I heard all of Mr. Van Diest's testimony, both upon direct and upon cross examination. Generally speaking, I am prepared to accept as my own testimony what was stated by Mr. Van Diest, upon cross examination as well as upon direct examination. The answers which he made upon cross examination to the various questions propounded are practically the answers which I would have made if I had been subjected to cross examination and the same questions asked me.

I have been a public utilities commissioner since the commission was created in 1910. So far as it was possible, I have scrupulously endeavored to observe the duties, obligations and restrictions imposed upon the commission by the terms of charter section 264*a*. That section required the commission to offer to the Denver Union Water Company the sum of seven million dollars in certain bonds of the city for all of the property which had shortly prior to that time been appraised at $14,400,000. That offer was made, but it was not accepted.

784 Section 264*a* further required that in case said offer was not accepted, the commission should proceed to construct an entirely new and independent plant for the sum of eight million dollars, and provided for an election on the subject of issuing bonds to said amount, which election was to be and was held on the first Tuesday in September, 1910 and the bonds authorized.

I entered upon the discharge of my duties as public utilities commissioner on May 31, 1910. Between that date and the bond election the commission made an estimate—I don't know whether you could call it an estimate, although it was an estimate in a way too, but without surveys—of the actual value of the water works system or plant of the Denver Union Water Company. It was made under circumstances which prevented myself and the other members of the commission from making a reasonable investigation of the question, because time was short, and particularly because funds were lacking. That investigation—if it could be called an investigation at all—was, under the circumstances, necessarily extremely superficial. From that time up to the time in August, 1913, when the commission appointed this board of engineers, neither the commission nor anyone on its behalf made anything like a thorough study or investigation of the value of the plant. An opportunity was offered from time to time, parts of the plant were visited and examined, but no estimates of cost or value were made in that connection. In reality, the first real investigation made by or on behalf of the commission was that which began in August, 1913, and was concluded in January, 1914, when the committee of engineers, in-

cluding myself, entered upon the work and made the reoprt which has from time to time been referred to in this testimony.

At the time when I was elected a public utilities commissioner, and during the summer of 1910, and up to the time of the bond election in September, 1910, I entertained an opinion in respect to the value of the plant of the Denver Union Water Company different from that which I have expressed in my testimony here and which is expressed in the report of the engineers of the Public Utilities Commission. I had expressed that opinion in a public way. The opinion which I then entertained and had expressed was that the value of the water plant was very materially less than that which I have now, upon investigation, determined it to be. Upon my subsequent careful, and at least extended, investigation I have found reason to change my original opinion.

During the summer of 1910 the commission employed an engineer, by name Mr. Hiram Phillips. What Mr. Phillips was then doing was to give the commission an estimate on the cost of
785 building the new and independent city plant proposed by section 264*a*. I think that was the main purpose for which he was employed. Mr. Phillips did not spend very much time in that employment—about one month. My recollection would be that he devoted most of that time to estimating the cost of a new plant. I recall that he visited parts of the water company's plant, but that is all, I think, and those visits could not have taken more than a week or ten days time altogether, possibly not that much. Since that time Mr. Phillips has never at any time investigated for the Public Utilities Commission the question of the value of the existing plant of the water company.

The committee of engineers of the Public Utilities Commission commenced its work upon the investigation of the property of the water company and its value some time in the month of August, 1913, and continued it until about the middle of January, 1914. The work was diligently prosecuted. We found it a pretty large job. It takes a long time, and a great deal of continued and difficult and hard work to investigate and try to ascertain the value of a large and complicated plant and system, such as this one. We would have liked considerably more time for the work. We were being urged to complete it, and the members of the commission were concerned about the amount of money that it was costing.

In our estimate of value we included nothing on account of water right values, as distinguished from land values, but as to certain lands which we valued and included in our total, we valued those particular lands as being lands with water. The sum of $93,312 mentioned in Exhibit 54-25, page 8, as "Water Right Values Included" designates the water right values included by the public utilities engineers in these land valuations. That is the total amount which we so included. The details of those inclusions are as follows:

Name.	Allowances. Acres.	Rate.	Amount.	Deductions. Acres.	Amount.
Phebe Strong ranch	126	$60	$7,560	126	$7,560
Wm. Strong ranch	145	60	8,700	145	8,700
Becky Archer ranch	130	60	7,800	130	7,800
Frank Archer ranch	320	60	19,200	320	19,200
Harriman Lake lands	130	25	3,250	130	3,250
Marston Lake lands	740	60	44,400		
Platte Canon reservoir	80	20	1,600		
Harriman Ditch intake	11.84	25	296		
Woodbury lands	20	25	500	19	475
			$93,306		$46,985

786 Except as to the values which I have now described, which were included in those land values, we did not include in our total valuation as found by the committee anything whatever on account of any water right owned by The Denver Union Water Company. We valued land with an adequate water right at about $125 to $150 per acre. We valued the adequate water right at $60 per acre, leaving a land value of from $65 to $90 per acre; but I know of no land without water that we valued at from $65 to $90 per acre.

So far as Armour C. Anderson and Carper had placed values upon these lands, our committee adopted them. I believe that Mr. Anderson and Mr. Carper testified, particularly as to the ranch lands, that they valued them with "slop over" rights only meaning the right only to such water as was available from the Platte Canon ditch after satisfying the demands of the water company for the service of the city. But that was not our understanding at the time we placed our value upon the lands. I think $60 per acre is enough for any adequate water right. The right such as you term a "slop over" right is in my opinion worth very much less than that.

In our estimates we added nothing to the value per acre of any of the lands valued by Anderson and Carper on account of water rights. We simply took their values and incorporated them in our total value. But we understood them to be with satisfactory water rights.

We included in our valuations both the irrigated ranch lands and paving over mains. Whether or not the ranch lands should be included depends upon the legal question as to whether it is advisable to retain them to fully protect and conserve the water rights. Of course if the ranch lands are excluded, the income and outgo connected therewith should likewise be eliminated.

In our valuation nothing was included for the right of carriage of water; on account of water rights only the value of approximately $93,000, as stated above, in connection with land values; for the item of going value no allowance was made, unless the fact that the plant was a going plant was taken into consideration in making

any allowance at all—I mean by that that if it were not a going plant and was not furnishing water it would be valueless. We have added nothing for going value unless the item of development expense ($375,000) may be considered as a part of the going value. I have no doubt that in a purchase case a water plant which has been assembled, and which is actually engaged in furnishing water to a very large number of customers, and which has been so engaged for a long period of years, possesses, by reason of that fact alone, more value than a water plant which has no business
787 and no customers. As to a rate-making case, there is doubt in my mind. When I say it is more valuable, I mean it is worth more, taking all things into consideration; power to furnish water, power to serve the purpose for which it is planned; its efficiency, its cost, and taking into consideration all of the elements of worth for the purpose for which it is planned. As to the cost of bringing a plant to that condition of effectiveness, to the situation of being a going concern, I think in many cases the expenditure of money, time, energy, etc., necessary for that purpose may have been compensated for in other ways. The parties may have been reimbursed. I think that is especially likely to be true in the case of a water plant, more so than in the case of a tramway, gas or electric company. Aside from the rates, the parties may have been reimbursed by the issuance of bonds, or by an issue of stock; or at least in part by charging to maintenance and operation the expenditures which have been made for development, and particularly legal expense. In the case of The Denver Union Water Company, I have no knowledge that the company has been reimbursed in respect to the cost in money, time and effort of establishing its business and bringing it to the point where it is a going concern.

In my judgment, whether going value should be included in a rating case is strictly a legal question. Nevertheless in the present valuation we have excluded it except as it may be included in the item of development expense. There is in my judgment a difference between going value and development expense. In addition to development expense, there is in my judgment a going value, which in a purchase case should be taken into consideration. What the amount of it is or how it should be arrived at I am not posted upon at this time. If the water company at this time actually had a de-nite franchise and a definite contract with the city, I would give it an added value, which I would not call a going value, but rather a franchise value. It would be what the board of appraisers in 1908 called "Business Value" and upon which they placed a value of $100,000. As to the other item upon which the old board placed a value of $1,100,000, I think I would give it such value as we did here in the case of development expense. I think our item of development expense has to do with that value. I think it is an adequate allowance to include that, as well as the other items which it covers.

Exhibit 54, sheet 6-*a*—items which are specifically listed in Exhibit 23: I think these items are not essential to the plant. They

were deducted upon that principle. Some of them are actually used to some extent; that is true of the West Denver pumps. I have not very definite information at hand as to how much use has been in the past and is now being made of those pumps.

788 Some one made the investigation some seven years ago, and we were told at that time that they were used very little. But I have no definite information upon it. I am under the impression that seven years ago, at the time of the former appraisement, we got all the data that we could upon the subject. As to what has occurred in that respect during the last seven years, I made some inquiry of the pump men—engineers, as to the amount the pumps had been used for pumping purposes, but I do not recollect that I obtained anything definite as to the extent to which they had been necessarily used. I do not know that these pumps have been used practically constantly for the purpose of pumping the supply at that station, and that they have actually pumped between 30 and 40 per cent of that supply.

As to the Platte Canon pumps, I believe that they are not actually used, except that one is occasionally used as a sand pump. We excluded them on the theory that they are not at all necessary to the plant. We made some inquiry concerning those pumps from the men at the plant. I could not state just how specific those inquiries were.

Exhibit 54-25, page 1: I stated on direct examination that from my best recollection all of the deductions made on that page were properly deducted. Such deductions really result in the exclusion of a number of things which were actually included in our own total valuation. Our valuation was made as a purchase proposition. Regarding some of the things included by us, I stated that I did not feel sure that they should be included. This valuation was made for the purpose of establishing a rating base. The conditions are a little different. It is a question of law as to whether the deductions made on page 1 of Exhibit 54-25 should actually be made in determining a rating base. I intended to so state. When deduction is made of item 2, page 1, Exhibit 54-25, the result is to take out of the valuation of Metcalf and Anderson everything which is covered in our valuation by the item development expense.

Item 3, Exhibit 54-25, page 1, amounts to the deduction of a considerable number of items of property which we did not exclude in our valuation. In our valuation, which was for purchase purposes, we rather gave the benefit of the doubt to the inclusion, while in the rate making case, unless they were strictly necessary—really necessary in the operation of the plant, we thought it wiser that they be left out. I mean strictly necessary and actually used and useful in the present day operation of the plant. That was the theory upon which I gave my assent to the exclusion here of things which had not been excluded in our own valuation.

789 The matter of excluding the ranch lands depends upon the solution of the legal question mentioned a short time ago. The exclusion of the Lake Archer and canal lands and tail race

depends upon the propriety of excluding the water power pumps at the West Denver station.

Exhibit 54-25, page 1, item 7, covers the exclusion of paving over mains, which we included in our own valuation. Concerning that, I have already expressed the theory that whether said deduction should be made involved the solution of a question of law, which I did not feel competent to determine.

According to Exhibit 54-19, the value of Lake Cheesman land and structures as determined by us is $1,096.969. According to my Exhibit 44, page 38, the value of Lake Cheesman as a water producing entity is $1,400,000. That means a net value of water rights for irrigation purposes of $303,031. The reservoir is now full, and contains approximately 80,000 feet of water. The total net value thus arrived at means about $3.80 per acre foot for the water at present actually in storage.

Exhibit 55 explained. I do not know of any precedent anywhere for the use of such a method as that for determining development expense. It is considered as simply illustrative, and as perhaps a little more detailed and proper way of going into the details than that shown in the report made to the Public Utilities Commission. I would consider the method equitable if the assumption is correct that at the beginning the value of the plant was represented by the outstanding bonds, and if the further assumption is correct that the additional bonds afterwards issued fairly represent the actual additions to the plant. If the original value actually exceeded the bonds outstanding, or if the actual additions were in excess of the amounts of bonds afterwards issued, I would say that the actual amounts of outlay ought to be used.

My own opinion is that the depreciation allowance ought to be deducted annually, although the fact is that that depreciation allowance must be reinvested in the plant for renewals. That is a point upon which authorities differ widely.

The assumption made in this table is that not only are actual additions and extensions to the plant covered by the new bonds issued, but also the renewals and replacements. The assumption is that the additional issues of bonds reimbursed the stockholders for the additional money which they may have put in, no matter whether it was a reinvestment or depreciation allowance or of other money. In other words, that the new bond issues which we made from time to time were sufficient both to keep the plant up and provide the renewals and replacements and also make the additions and betterments. I think you can properly treat the annual
790 depreciation allowance as a repayment of capital, and so deduct it each year from the capital account, and yet not regard it as an investment of new capital to be added to the capital account when it goes back into the plant.

This is simply a method of getting at development expense for a certain period of years. I do not believe that it could be carried on indefinitely in any case. If carried on for a long period of years it might lead to absurd results. Therefore it can be used, as used

here, simply to determine development expense during the early part of a plant's life.

Theoretically, the real function of a depreciation account, such as is provided in said Exhibit 55 by the one per cent annual allowance, is to reimburse the investor at the time of the amortization of the plant for his loss. Depreciation which is to be covered by such an allowance is often made up to a large extent by property which has to be abandoned in the course of the service by reason of being worn out, or by reason of change in the art or obsolescence from one cause and other. That is depreciation as much as the reduced value of the parts still remaining in service caused by their actual accrued depreciation. The theory of this depreciation allowance is that at the end of a given period the owner and operator will be entirely reimbursed for all depreciation, not only the accrued depreciation upon the property still remaining in the plant at the end of the period, but also the accrued depreciation which has occurred by reason of necessary abandonment of property during the period of service. The total allowance for depreciation made in Exhibit 55 amounts to $1,547,652. The accrued depreciation upon existing property, shown by Exhibit 54-19, sheet 15, as determined by the Public Utilities engineers, was $1,072,477. In addition to that, the property necessarily abandoned during the period of service, as shown by Exhibit 14 and by the testimony of Mr. Metcalf amounted to $1,261,000, not including the Sullivan reservoir. Adding that amount to the accrued depreciation on existing property, as determined by our Committee, produces a total of $2,333,477, and if you add to that the Sullivan reservoir, approximately $194,000, which we treated as abandoned property and excluded, an actual total depreciation on the plant during the period is arrived at which would be much more than would be covered by my depreciation allowance as made in Exhibit 55. Abandoned property is depreciation, and must no doubt be taken into consideration, but I would have to look at the list of abandoned property and give it some study before I could draw any conclusions upon it.

791 According to the determination of Metcalf and Anderson, the accrued depreciation upon existing elements of the plant, plus the property abandoned during the period, results in a total depreciation for the period of $2,785,000. It appears therefore, that either upon the basis of depreciation as determined by our committee or as determined by Metcalf and Anderson, the depreciation allowance which I have made in Exhibit 55 is insufficient to amortize the loss by depreciation and make the owner and operator of the utility whole at the end of the period. If therefore depreciation allowance must in my computation be increased, the result obviously will be to very considerably increase the deficit or the sum of the deficits in income and decrease the sum of the surpluses, and thereby greatly increase what I call development expense as shown by said Exhibit 55.

That would be true unless the $7,000,000 with which we started the computation exceeded the actual value of the investment at that time sufficiently to offset the error. On the other hand, if at the beginning of the period the value of the property exceeded $7,000,000,

then my table in Exhibit 55 would be erroneous for that additional reason. To take care of all depreciation, not only in existing elements, but in abandoned property, the depreciation allowance in Exhibit 55 would have to be increased from one per cent per annum to about one and one half per cent per annum. I do not know that that would increase the final deficit. I am inclined to think that it would have the opposite effect. I have not made the computation and do not know that the result would be to increase the deficit or development expense, now shown on Exhibit 55, to a sum upwards of $900,000, but I presume that is correct.

Exhibit 55 limits additions to capital account to additional bond issues. If new investments were made in the plant of moneys not realized from bond sales, they should be added to capital account.

Exhibit 55 also entirely ignores any increment in value, if any such increment has occurred. It deals solely with actual cost, measured in terms of actual investment from bond sales only.

We failed to include in our valuation anything on account of water rights, except said sum of $93,000 of additional value to certain lands, because the matter involves a legal question. The theory was that in valuing this property we should, so far as possible, go back to the conditions which prevailed at the time of the acquirement of the property and value it now under the same conditions and upon the same theory as it was then acquired. That being our theory
792 and our method, what we actually did was to value only those water rights which the company had acquired by purchase and not to value at all any water rights which the company had acquired by original appropriation or otherwise than by purchase. It was considered that the cost of acquiring those water rights was taken care of in the way of legal and operating expense and paid for in that way: that they were acquired by virtue of the authority granted by the people of the city to act for them, and that so far as those rights were concerned the Company was properly a trustee for the city. That method and that theory related to all of the water rights of the Company, except the irrigation rights pertaining to the Platte Canon ranches, the irrigation rights which we assumed pertained to the Marston Lake and Platte Canon reservoir lands, and one or two smaller items of that sort, amounting in the aggregate to $93,000.

As to all of the rest of the water rights, as assumed that whatever actual cost had been involved in their acquisition, the company had been reimbursed therefor by charging it to operating expense or maintenance, and that as to the property right itself, the company held it as trustee for the city. If I should happen to be wrong in that solution of the question of law involved, there might be something to be added on account of water rights to the sum of the values which are specified in our Exhibit 54-19, but I would not undertake to say how much.

Under date of August 20, 1910, shortly prior to the bond election, the Utilities Commission put out a printed report, to which the names of myself and the other members were signed.

As of December 31, 1910, the commission published its annual report, which was printed. In that annual report, speaking of the

prior report issued on August 20, the commission stated: "Under date of August 20, for the purpose of informing the public as to its findings prior to the holding of the election on September 6th, the commission submitted to the public a preliminary report embodying a review of the official action of the commission to date." (Objected to. Objection overruled.)

The report of August 20, 1910, was made, published and promulgated by the commission just prior to the bond election for the purpose of informing those who were to vote on the bond question, so that the matters set forth in the report might be considered in their determination of what their action should be. In that report, and also in the annual report of December 31, 1910, we took up the appraisal made by the former board of appraisers which resulted in the valuation of $14,400,000. In our said reports we stated: "The total given by the board of appraisers for the physical plant is
793 $10,354,075; our estimate as given above is $5,405,000, or only about one half the amount estimated by the board of appraisers. Our reasons for this estimate are somewhat more fully shown in the report issued by our consulting engineer." (Objected to. Objection overruled. Exception.)

As to the item of water rights which had been separately appraised by the former board of appraisers, we stated in those reports in substance and effect that no valuation should be assigned to them because as a legal matter the company had no title to the water or the water rights, but those belonged to the consumer and not to the corporation. In our present valuation, except for the item of $93,000 incorporated in the land values and mentioned above, the theory in respect to the water rights was essentially that so expressed in our former report.

In our said reports of August 20, 1910, and December 31, 1910, in respect to the item of business and going concern value, which the former board of appraisers had valued as a separate item, we said: "It is undoubtedly true that some credit should be given to the business and going concern value, however, as defined in the report" (meaning the report of the board of appraisers), "as 'representing the added value of the plant because of its connections and business, and because the parts are united into one system and are tested and in successful use.'" I still entertain that view and think that some credit should be given to going concern value.

In our report of August 20, 1910, referring to the same subject of going value, we stated: "Assuming however, that a generous allowance should be made for the business value of the plant, and placing this value at $1,000,000, which in our opinion is at least twice the sum that should be used in making this estimate, we would have as a total $6,405,000 as the entire present value of the plant. These estimates we believe to be greater than actual conditions justify; it is credibly reported to this commission, in fact, that the original cost of the present plant was less than $5,000,000, and if that is the case, its present value, owing to depreciation, cannot be more at the present time than $4,000,000 at the very highest. If, in addition to this, we add, as is frequently done, ten per cent for the going concern value, we would have as the total present value of the plant $4,400,000."

We incorporated in our report of August 20, 1910 a report which had been made by Mr. Hiram Phillips, under date of August 1910, and made his report our own so far as it went. In that report of Mr. Hiram Phillips, so made a part of our report, it was stated:

794 "I recognize that the Company's plant, with all its imperfections has a positive value beyond its physical worth; it is a going concern."

In the conclusions which appear under that heading in the report of the commission of August 20, 1910, we stated: "The principal questions before this commission at the present time therefore are these: Was the amount of $7,000,000 in bonds offered to the water company sufficient to constitute a fair and reasonable remuneration for its plant; and, second, will the bond issue of $8,000,000, if sold or issued at par, as required by the Charter Amendment" (referring to section 264-*a* of the Charter), "furnish sufficient funds for the construction of a new plant, adequate for the supplying of the needs of this city at the present time? To both of those questions we give affirmative answers. We believe that the present plant of the Denver Union Water Company is worth less than $7,000,000 as a water supply to the city and county of Denver and its inhabitants, and we believe further that an adequate system, capable of furnishing a satisfactory supply of water to the city for the immediate future, can be constructed for $8,000,000. * * * In making these estimates, however, we have, we believe, erred, if at all, on the side of generosity to the water company, and we are convinced that the estimates we have made are conservative and safe. * * * We are confronted by the necessity of immediately constructing a new plant or permitting the water company to go on, entrenching itself more strongly and bringing the people of this city and county into political and financial bondage to a greater and greater extent from day to day and year to year. * * * The question then is resolved into this: Shall the people own or be owned? And to this question we believe there will be but one answer. Respectfully submitted, The Public Utilities Commission of the City and County of Denver, by Armour C. Anderson, President. Edwin Van Cise. A. Lincoln Fellows. Denver, Colorado, August 20, 1910."

By reason of my recent investigation, I have, as stated above, found it necessary to change my opinion in respect to the value of the water company's plant.

In our present valuation the lands which we have valued with water rights are those which according to our judgment and opinion were originally acquired and paid for by the company as lands with water rights. But the values which we have assigned to such lands represent what in our judgment is the prseent day irrigated land value, without regard to the original actual cost to the company.

795 Redirect examination:

The haste to which our committee of engineers was subjected in their work did not prevent them from making a complete investigation, except for those failures to re-calculate and correct which Mr. Van Diest has mentioned. . Inclemency of the weather and deep

snows prevented us from making additional excavations on the pipes and conduits which otherwise we had intended to do.

In incorporating into our valuation the values assigned by Armour C. Anderson and Carper to the ranch lands, we assumed that Anderson and Carper had carried into the value of the lands water right values at the rate of Sixty dollars per acre on the well irrigated land.

Recross-examination:

Our Committee, however, did cause to be made a considerable number of excavations along the lines of the conduits for the purpose of making an inspection of their physical condition. We made about forty such inspections. We had planned to make about one hundred, but we did succeed in making about forty. The excavations were made at points designated by the Committee and in the manner ordered by the Committee.

In determining the depreciation of the conduits and the other portions of the physical plant, we depreciated in accordance with the physical condition as we found it. With the exception of some portions of the distribution system, we found that all parts of the plant had been constructed since 1890, except a small portion of it which was constructed in 1889.

There were some parts of the distribution system which had been laid prior to 1890, concerning which the records do not disclose the exact year in which it was laid.

W. L. REYNOLDS, a witness for the defendants.

Direct examination by Mr. Nye:

Assistant engineer for the Public Utilities Commission; graduated from University of Colorado in 1909; has been connected with the Public Utilities Commission since April, 1914. Most of witness' experience has been in engineering work, and in 1911 was engineer for the Glenwood Light & Water Company; is now familiar with records pertaining to water and water rights in the state engineer's office. Witness prepared figures in Mr. Fellows' Exhibit 44; Fellows instructed witness to get all information from state engineer's
796 office and other places that would help to a definite conclusion in regard to Platte river; went through all the records, copied some, talked with division engineer and water commisioner of district 2, took all the information to Mr. Fellows and together worked up some preliminary tables to find out what the stream flow of the Platte would have been on an expanded table, and found that the year 1913 was a 113 per cent year, using a mean as a basis. Mr. Fellows determined the basis to be used. Witness' work was merely clerical. Took the basis determined by Mr. Fellows and did the arithmetic of it. Working with Mr. Fellows, it was determined that if a man owned a ditch in districts 2 or 8 and put in a crop, and did not get water in 1913, he would have little hope for water in putting in another crop. We would consider his demand a legitimate demand; anything past that would not be considered a demand, and 1913 was taken as a basis.

With that as a basis the tables were worked out. Witness is responsible for an error in table 4, page 3 of Exhibit 44, in the month of December, 1902; explains how it arose; was merely a matter of arithmetic. Witness has compared testimony of Anderson, Comstock, Bull, Field and Fellows, and has constructed a table of comparison.

Exhibit 47 marked for identification. That is the table of comparison of estimates of above-mentioned witnesses—just a mere tabulation of the testimony of the witnesses.

Further explains Exhibit 47. Where the available storage exceeded capacity of the reservoir, the witness substituted capacity of reservoir in certain columns; it was merely a computation.

The first note at the top of the exhibit was prepared by Mr. Fellows; the second note prepared by the witness.

Objection to the exhibit overruled.

Cross-examination by Mr. Dorsey:

Fellows prepared first three paragraphs on page 1 of Exhibit 47, and also the notes following the words: "Anderson" and "Comstock." The note following the word "Field" was prepared by Field, the note following the word "Bull" was prepared by Bull, and the note following the word "Fellows" was prepared by Mr. Fellows.

Witness prepared note on the water commissioner's reports on Exhibit 44; in arriving at stream flow in South Platte, certain basic figures were taken, and to that was added the amount that had been actually stored at Lake Cheesman, and the basic figures were taken
797 from records in the state engineer's office kept in loose-leaf notebooks, according to division; the loose leaves are the original records.

Cannot at this time give the mean flow expressed in second-feet that was taken for the months of April to October, inclusive. Witness explains way stream flow for January, 1902, was built up, as follows: On page 2, table 3, from the averages, we have January; the flow at Cheesman would furnish about 24 per cent of the flow at Platte Canon; the flow at Cheesman for January is given at 3,812 acre-feet, which would give 15,900 acre-feet as the flow at the canon, or a mean flow of 260 acre-feet for the month of January, 1902; had no actual records for that month.

We have actual records for January, 1910, showing 12,277 acre-feet for the canon, which would be a less average flow per second-foot. In preparing the records, witness talked with Mr. Field, state engineer, who was a witness in this case; Mr. Field only told witness where to find records. Mr. Fellows determined the basis on which the computations were based; that basis was, first, that 1913 was a fair year upon which to base an expected demand; second, that the Platte river under ordinary circumstances would take care of itself below Clear Creek; in other words, that the St. Vrain and the Big Thompson are needed to supply upper district 1. This had reference to the critical time of the irrigation season. It was assumed that none of the stream flow of all the side streams, running into district 2, except Clear Creek, were needed for the supply of district 1. This assumption was made as to the critical periods in the irrigation sea-

son. Other periods would take care of themselves. "Critical periods" means periods of heavy irrigation.

Witness was instructed by Mr. Fellows to use only Clear Creek and the side streams above as available to districts 2 and 8, and this assumption was applied uniformly; in tables 7 and 8, the inflow into districts 2 and 8 from tributaries and seepage was obtained from records in the state engineer's office, except where indicated by a star; those designated by a star were estimated and given to witness by Mr. Fellows; the figures appearing under the words "Cherry Creek and seepage" might have been designated by a star; they were estimated, but assumed to be uniform.

Whatever water commissioner's report said in respect to Cherry Creek would be incorporated. Does not know how the water commissioners estimate the seepage. Seepage measurements are taken down the Platte river from the mouth of the canon through to the state line. The water commissioners seem to be informed
798 about what the seepage was for the previous year, and they estimate it uniformly.

Seepage measurements ceased from 1909 until 1913, and in those years water commissioners took the 1909 figures, but witness checked it up with 1913. The first seepage measurement in 1913 was taken in October, and those would not be available for reports prior to that time; water commissioners' estimates compared favorably with the 1913 estimates. The measurement at the 16th Street bridge, which would practically include district 8, showed to be 70 feet return the total from the canon down to the end of district 2 showed 371 feet, or 301 feet in district 2.

Is not sure that measurements were made in 1909. Knows that a measurement was made in 1908. Water commissioner states that seepage varies from month to month; they do not make an actual determination. In the month of October, 1913, water commissioner's average seepage result was 293.9 second-feet, which compares favorably with the 1913 measurement of 301 second-feet. The range of water commissioner's estimates during the year was from 250 to 300 second-feet of seepage. The measurement of October, 1913, is given as a strictly seepage measurement, but probably covers more. It excluded tributary inflow, and included the sewers from Denver.

Table on page 7, Exhibit 44, being table 8, under the heading "Seepage" covers seepage and inflow from the Denver sewers. Witness treated sewage as seepage.

Does not know whether the sewage of Denver was included in the seepage measurements. Sewage would be considerable, and is of constant flow, particularly in the summer months; never measured it. Witness tabulated figures under Mr. Fellows' constant supervision, and in that way made table No. 9, which relates to the actual diversion in 1913—page 13 of Exhibit 44.

It was witness' intention to tabulate Last Chance ditch exactly as it occurs in water commissioner's report. In May and November, 1913, the witness took average flow reported for the Nevada ditch, and averaged it out over the full number of days in each month,

although the water commissioner reported that it flowed only for a part of the month; got the figures from the water commissioner's pocket notebook. There is only one statement in that note book concerning the Nevada ditch for the year; that was made at the end of the season, and reported an average flow of 55 second-feet, and a maximum flow of 55 second-feet; and the same condition existed as to the Last Chance ditch, but in addition it is reported that on two occasions the Last Chance was shut down. Re-
799 ferring to table 13 of Exhibit 54, got the figures from blue-print furnished by Mr. Hawes of The Denver Union Water Company. They are supposed to refer to actual diversions by the company in the year 1913 through the Platte Canon ditch. The High Line canal was included in the tabulation furnished by Mr. Hawes, but all the figures appearing in the table were in the tabulation given by Hawes, except the last column, which covers expansion to acre-feet.

Mr. Hawes' tabulation did not state whether the Platte Canon ditch diversions were for irrigation purposes or otherwise, and witness does not know.

Witness produces stream-flow records upon which the estimate of discharges appearing in table 4, page 3, of Exhibit 44, were made up, for the months of April to October, inclusive, 1902, expressed in acre-feet and in average second-feet, as follows: April, 15,507 acre-feet, average 261, second-feet; May, 11,103 acre-feet, average 181 second-feet; June, 7613 acre-feet, average 128 second-feet; July, 6248 acre-feet, average 85 second-feet; August 4979 acre-feet, average 81 second-feet; September 4861 acre-feet, average 82 second-feet; October 3792 acre-feet average 62 second-feet; November, 1081 acre-feet, average 50 second-feet. In arriving at the figures set down in table 4, Exhibit 44, there was added the quantities stored in Lake Cheesman each month, as shown by Exhibit 31, and whenever in any month an inflow into Cheesman was noted and no outflow was noted, the inflow was considered as actually stored and the addition to the figures was arrived at in that way. The notes on Exhibit 47 under the heading "Notes" were taken from the reports of the water commissioners—some from the weekly and some from the bi-weekly and some from the annual reports, or the field books. A note of precipitation record in the month of September was taken from precipitation records; the notes are not quotations from the water commissioners' reports, and witness tried not to introduce conclusions. Witness says notes selected from the water commissioners' reports were not selected to support the defendants' Witnesses as against the plaintiff's. When asked to give an instance where a note supported the plaintiff, referred to the year 1903, month of June.

Witness did not intend to cite notes merely to cut down high storage estimates.

Did not instance any note which would tend to show conditions favorable to storage. Wherever any such notes were available, they were omitted.

The average of the different witnesses shown in the comparative

tables Exhibit 47, are not for the same periods of years. A change in the periods would make a change in the results. Evapora-
800 tion was not deducted from any estimate in Exhibit 47.

Redirect examination by Mr. Nye:

Page 4, Exhibit 44, table 5, no change to be made in the year 1902. The data for the years 1900 to 1908 on that table are derived from loose leaf books in the state engineer's office. Since 1908 they have not been kept up to date; did not compare the loose leaves for that period with the water company's records.

Recross-examination by Mr. Dorsey:

The records of Cheesman flows kept by some representative of the water company and sent to the engineer.

W. L. REYNOLDS, A witness for defendants, recalled.

Direct examination by Mr. Nye:

Exhibit 56 shows representative ditches in lower Platte region, including Brantner, Fulton, Brighton and Farmers Independent, and the use which they made of water from the year 1908 to the year 1913, inclusive; it is shown by months and summarized by years. The solid line indicates the amount of water actually diverted each month; the broken line is uniform in all months, and shows the drafts during the months of May, June, July, August, September and October to yield 1½ acre-feet of water per acre; the drafts are figured on the following percentages: 15 per cent in May, 25 per cent in June, 25 per cent in July, 20 per cent in August, 10 per cent in September, and 5 per cent in October.

Illustrates page 6 of the exhibit. There were 3271 acres irrigated, 12,219 acre-feet were used, or 3.74 acre-feet per acre. These figures were taken from the State Engineer's records, and the actual amount of water diverted for each month is shown on this diagram as shown by the State Engineer's records. The acre-feet are figured from the second-feet per day, shown by those records; calculated that one second-foot for twenty-four hours would furnish 1.98 acre-feet.

The acre-feet supplied each month per acre is arrived at by dividing the total number of acre-feet supplied by the acres irrigated for that particular month. The last column of the table carries the percentages for particular months in reference to the total used for the year.

On page 10, the figures on the other tables are carried forward, so far as they are material, to show at the end of each month
801 the total amount of water, in acre-feet per acre, that has been used up to that time.

The theoretical supply for a single month does in one or two cases exceed the actual supply for the same month, but in all other cases the actual supply exceeds the theoretical supply. In the treatment of the actual supply, has commenced with the month when the diversions were actually made.

Further explanation of tables.

Continues explanation of tables.

Exhibit 56 offered in evidence. (Complainant objects thereto. Objection overruled.)

Cross-examination by Mr. Dorsey:

On page 6 and the following three pages the actual diversions of the various ditches are shown; the quantities diverted are taken from the water commissioner's reports. Those reports do not show whether the water actually taken through the headgate was actually applied to the lands.

FREDERIC W. TAYLOR, a witness for the defendants.

Direct examination by Mr. Nye:

Now devoting attention to his own farms and property; has always been interested in agriculture or horticulture work; professor of horticulture in University of Nebraska for eight years; had charge of extension work in Farmers Institute; spent 8 years with the Government exhibit in similar work at Omaha; chief of the department of agriculture and horticulture and irrigation and forestry at Omaha exposition, and in similar work at Buffalo exposition; was in charge of horticulture and agriculture at St. Louis previous to the opening of the exposition; visited Europe half a dozen times as special agent of the Department of Agriculture, studying conditions. Brought to this country the Kherson oats, from southern Russia; in service of Phillippine government, where was director of agriculture; owned land in Nebraska for twenty-five years.

In 1909 and 1910 was connected with large concern called Tri-State Land Company, having holdings of 32,000 acres of land and water rights on North Platte river. Spent about $200,000 building ditches and completed diversion dams across the North Platte river, and made arrangements for getting a sugar-beet factory; sold a million and a quarter dollars' worth of land; the company owned 32,000 acres; the ditch was completed with a capacity and had decrees for 80,000 acres; came to Colorado to live in the early part of 1907.

802 With J. G. White & Company on the Denver Reservoir Irrigation Company's scheme; made reports thereon for J. G. White & Company; then withdrew from Colorado and completed work in Nebraska and returned to Colorado.

Examined projects in all the irrigation states except California and Nevada; was appointed joint receiver of the Denver Reservoir Irrigation Company with Mr. Quigley; resigned to give way to Mr. Arthur Day; then went to Philippine Islands; is familiar in general way with the South Platte river and districts 2 and 8; knows roughly the boundaries of those two districts.

Has known the territory served by Brantner, Brighton, Fulton, Farmers Independent and Burlington ditches for a number of years; knows the English High Line ditch; owns four farms in Colorado,

two of which get supply from Standley lake and Marshall lake, other two from Farmers High Line; the latter takes its water from Clear Creek, near Golden. Two of the farms are 160 acres each, one is 95 and the other 45 acres; the two smaller ones are under the Farmers High Line and the two quarter sections are under Standley lake.

Within the last few weeks has made a number of examinations and studies of the situation on the Platte river from Denver twenty or thirty miles down; spent two or three days in the neighborhood of Fort Collins and Greeley, where most of the lands are watered from the Cache la Poudre, with the object of finding out what lands with water rights in various localities are worth, and what water itself sells for for irrigation purposes. In making investigation witness had Exhibit 40 before him.

Speaking from Exhibit 40, and comparing the Brantner supply with the assumed Cheesman supply, witness says that Brantner ditch gives an evener supply, less variation, than Lake Cheesman, and would say that Brantner was a better supply; the same answer as to the Fulton, Brighton and Farmers Independent. Thinks there is no difference between a reservoir supply and a direct supply, if it is only a question of being able to get from one the same amount of water as the other, on the same basis, during the same period. Knows of only two ditches along the Platte river that would be considered as needing a supplemental supply over the supply they now have, those are the English High Line and possibly the Burlington.

Brantner, Brighton, Fulton and Farmers Independent have all the water they have any use for, and from the charts in question, it would not appear that Cheesman lake could supply them
803 with water when they needed it, when their own rights could not supply it. Investigated the value of water rights under Brantner, Fulton, Brighton and Farmers Independent; started out with considerable knowledge of the conditions which he wished to prove or disprove; visited officers of the ditch to find out what their knowledge was, as to water used and regularity and price at which it was sold; went to state engineer's office, checked available data, and found it checked exactly with Exhibit 40. Made it a point to see actual users of water—farmers—under each ditch, and talked with them about their supply, regularity, price paid, etc. Talked with scores of people; information did not vary much; some apparent discrepancies were explained by methods of computation, or differences in form of expression; nearly always came out about right. Brantner ditch, one share evidences ownership of 11 inches; from state engineer's report, covering 11 years there was an average delivery of 3.3 acre-feet to each acre of land irrigated.

(Plaintiff's objection to witness' testimony as to value overruled.)

Brantner shares were worth $300; these shares give one inch for the acre; the market value for the acre would be $27.25, or $8.30 an acre-foot, on a basis of 3.3 acre-feet for the land irrigated. Fulton Ditch represented by shares, each share representing one inch of water for each one and three-fifths acres.

(Objection to testimony as to value of Fulton ditch shares over-

ruled.) Market value $65 to $75; price per acre, $42.80 per acre served, and $13 per acre-foot. Farmers Independent rights evidenced by shares, each share representing eight inches, one inch per acre; market value $300 a share, or $37.50 per acre, $9.17 per acre-foot, duty 4 acre-feet per acre; duty under Fulton ditch 3.3 acre-feet per acre.

Brighton ditch—not able to secure estimate of value. Farmers High Line, one of the ditches from which witness derives water, shares represent 10 inches for 30 to 40 acres; sells readily at $1,250 per share, which is its fair value; taking one share as sufficient for 35 acres, makes $35.60 per acre served; on the basis of actual delivery, as stated by the state engineer's reports, it would be $28.56 per acre-foot. Investigated ditches from the Cache la Poudre; examined Larimer and Weld County ditch, Larimer County canal, which is part of the Water Supply & Storage Company's organization; Larimer County Canal No. 2, commonly known as the Cache la Poudre, and Consolidated Hillsboro Ditch Company and the Home Supply ditch; and investigated these ditches in the same way as the ditches on the Platte. All these Cache la Poudre rights evidenced by shares.

804 Under the Larimer & Weld County ditch, a share represents 1.44 second-feet. (Evidence of market value objected to, overruled.) Market value $4,000. Users of these shares have two sources of supply: direct flow from the Larimer & Weld County ditch and storage from Terry lake or some other portion of the system. 1.44 second-feet used for each 160 acres, and two shares out of Terry Lake at $2,000 each, making his rights for the 160 acres cost $8,000, or $50 per acre, to cover both direct and storage supplies.

In that district it is usually considered that one share of direct-flow and two shares of storage is sufficient for 160 acres.

They grow a good deal of alfalfa, a considerable area of sugar beets, which take more water than ordinary cereal crops. With regard to Water Supply and Storage Company, when shares were originally issued, one share would be applied to 40 acres, but in practice one share is applied to 80 acres; the market value of $3,000 a share includes some stored water. This is sufficient supply to give an even supply throughout the season for agricultural service. Considering the share as sufficient for 80 acres, it gives a cost of $37.50 per acre.

Larimer County Canal No. 2, the shareholders get some direct water and some stored water; one share is used is serve 40 acres; market value, $2,000, $150 an acre; does not know the duty. Consolidated Hillsboro ditch, each share represents 50 inches, and is a water supply for 80 acres; market value, $1,800 per share; has sold as high as $3,000; present market value is $1,800.

There has been a decline in the demand. The market value, reduced to an acreage basis, would be $22.50 per acre; on basis of price of five years ago, it would be $37.50 per acre.

Home Supply ditch divided into rights; ten shares, constituting a right, are sufficient for 800 acres, but now each share considered sufficient for 80 acres; market value $4,400 per share, or $50 an

acre; character of crops raised under all the Cache la Poudre ditches about the same.

Witness not permitted to testify to income from his own ranches.

Witness not permitted to testify as to experience in selling water rights in Nebraska.

Witness had experience in selling water rights from Standley Lake system; started in 1907, selling a share of stock evidencing the ownership of 10 acre-feet of water; had several men working on it; sales went very slowly, so districts were organized and water sold in a lump to the districts, and payment taken in the form of district bonds; they were sold by bond companies, who called them
805 municipal bonds. Water rights were sold at $50 per acre-foot for the water, $500 per share of 10 acre-feet; could not say what amount was sold; it was very disappointing.

Not nearly all of the rights under the Standley lake have been sold. Assuming a reservoir such as Lake Cheesman, furnishing not less than 50,000 acre-feet per year for a period of ten years, and for four years less than 100 per cent, and taking into consideration knowledge of existing conditions along the valley of the Platte, witness thinks that the High Line ditch and the Burlington ditch would afford an opportunity to sell a supplemental supply, but not nearly all of the supply, and the rest would have to be sold for delivery into the general territory east of the Platte and northeast of Denver. Does not think anywhere near all of that water could be sold for supplemental supply.

There is plenty of land available to which it could be got within a safe distance—that is, a distance that it could be run without losing all of it, or a very large portion of it, from seepage. Does not think it could be sold in large quantities for cash. When asked to put a value on Lake Cheesman, witness says that he assumes that the farmers cannot afford to pay to exceed $50 per acre. Thinks that one and one-fourth acre-feet per acre is necessary, plus loss in transit; so that to make an accurate estimate, it would be necessary to know where the water was to be used, but assuming an average point of delivery under the English High Line and Burlington ditch, do not think loss in carriage would average less than 20 per cent, and estimates an acre-foot and a half of water for each acre to be served; then, cost of transportation must be considered, and the question of interest charge from now until the water could be old would have to be considered, but thinks it would be necessary to have an acre-foot and a half for $50, less cost of carriage, until it was actually sold, and the cost of transporting.

Assuming that the water is to be used on land under the High Line at the lower end, and the purchaser to pay carrying charges, would value the Cheesman water at $35 per acre-foot. There would probably be a loss of five to ten per cent, at least, in carrying the water from Cheesman lake down to the headgate of the Burlington ditch, and there is a considerable loss in the ditch itself; when you get 15 miles from the river there is sandy soil. Witness' estimates do not take into consideration cost of selling or evaporation. Cost of selling might be from ten to twenty per cent; would depend upon

conditions which are going to prevail. Does not think there is any existing demand which would not require a selling cost.

806 No irrigator can go to his headgate and draw water from a distant reservoir whenever he wants it; he must work in harmony with other users. There must be enough users at one time to make a decent run. If each one was supplied separate from the others, there would be a great loss in seepage. Water should be delivered in large quantities, of, say thirty to forty per cent of the capacity of the ditch in which it is run.

Witness also investigated the Burlington ditch, in which a share consists of four inches, each inch waters an acre; a share has a market value of $100; the duty of water is two acre-feet per acre; the value $12.50 per acre-foot or $25 an acre.

The Farmers High Line Company owns one reservoir, with a capacity of somewhere around 5,000 acre-feet, but nearly every user has his own reservoirs, which are mere distribution reservoirs for holding the supply as it is wanted. Company's storage is included in the $1,250 per share.

There is a supplemental supply known as the East Lake Water Company, which draws its water through the Farmers High Line, for about 1,000 acres; it is a separate organization.

Knows of Marston lake. Thinks the value for storage in that lake on a 40,000 acre-foot basis would be slightly but not much less than Cheesman lake. The water market is limited by the supply of land.

Thinks the land that could be irrigated by Lake Cheesman is divided up into small holdings of, on an average, not to exceed a section to the individual; there are some larger holdings of two or three thousand acres; more or less of the land is owned by people living in Denver, and a great deal owned by non-residents; such non-resident owners are not inclined to assume much of a burden to supply water to the land.

Cross-examination by Mr. Dorsey:

Witness 54 years of age; born in Nebraska, lived for 20 years in western Iowa; lived from 1887 to 1899 in Nebraska; became connected with the University of Nebraska in 1891; never engaged in anything but farming; father was a nurseryman, and witness followed that work until he was thirty; up to 1891 had no experience in irrigation; work in University was generally in promotion of interest in agriculture through the University agencies; stayed with the University until 1899; University work devoted in part to helping farmers in western part of the state, who depended on irrigation; visited Colorado during that time to study irrigation methods; in 1899 went to Buffalo.

Further details experience in connection with various Expositions, which continued until 1905.

807 Next went to Europe.

Had land in Missouri and Nebraska and central Illinois; has to drain Missouri land; investigated Denver Reservoir Irrigation Company for J. G. White in latter part of 1906; not sure of the exact

date, but spent ten days here. Made report to White at the end of the first trip; returned in May, 1907. At the time of first employment, company was incorporated; it had done nothing but have engineers' examinations and studies made; after witnesses' report, J. G. White & Company went into the Denver Reservoir Irrigation Company scheme; witness made a favorable report. J. G. White & Company expected to have all the engineering and construction work and to participate in the profits, if it should be profitable. They put in the only money that was put in during the early stages; they found the people who financed it.

Became manager in 1907; continued for two years; construction work was started and well under way at the expiration of that time.

Duties were particularly along the line of handling land, including purchase of the Denver Land Company, Marshall Lake, land that laid to the west side of the river, near the mountains; Marshall lake obtains water from South Boulder Creek; the Denver Reservoir Irrigation Company purchased it, including 20,000 acres. Witness' duty was to handle all this land and other land which was purchased—some out toward Hudson. The company operated some of the lands, and the rest are operated by the tenants.

Operated some land below Barr Lake, from the Barr Lake seepage. The Marshall lake and lands were acquired just before witness became manager. Hudson land acquired while witness was manager.

So far as these tracts were concerned, water was bought with the land.

At time witness left Denver Reservoir Irrigation Company in 1909, Standley lake had not had water; the whole system is not yet complete; after leaving the company, did some work for J. G. White & Company, in irrigation matters, some of them in Colorado, one or two in the neighborhood of Fort Morgan; made favorable report on the San Arroya project; it was a flood-water project; did not study it very carefully; did not study the water conditions so much as the land, but on other projects studied the land; does not disclaim any participation in examination of San Arroya water supply; worked out drainage area; has heard that the project was a complete collapse, and dismal failure, and a total loss all money invested, like many of them in Colorado.

808 While employed on Scotts Bluff project, made various reports; for two years was vice-president of the company owning the Scotts Bluff project; water supply came from the North Platte. At that time rights in the North Platte had not been thoroughly adjudicated, but were practically all appropriated; the ditch was the successor to a small ditch which had carried water for many years; water supply in the vicinity very well worked out.

The lands of the project lay a little above the Burlington railroad, Alliance branch; no reservoir connected with the system; some farmers had private reservoirs; part of witness' business was to sell the land.

Witness examined many projects for J. G. White & Company during that time; thinks one of these projects was located in the southern

part of the state, along the Arkansas river; don't think he examined any projects in Colorado; was appointed receiver for the Denver Reservoir Irrigation Company in June, 1910, and that continued a year; main canal of Standley lake, known as the Bull canal, was pretty well finished, and a considerable part of the laterals and a consideral part of the O'Brien canal, which takes water from the Platte, to Barr lake, and a considerable part of the construction of the extension of the Barr lake dam had been built during the receivership; the activities of the company were lessened on account of the receivership; considerable work was carried on for awhile, and then stopped almost entirely. During that time a deal was made with the Henrylyn district.

No offers were made to sell rights to individuals. The campaign for the sale of water to individuals was in the beginning of the year 1907, and at that time no work had been done; the project was simply a plan.

After retiring from the receivership, went to Philippine Islands; had something to do with the sale to the Henrylyn district during the receivership, and afterwards; remained in the Philippines a year and a half, a month of which time was spent on a visit to Denver; devoted that time to Denver Reservoir Irrigation affairs; no rights were sold during that time; left the Philippines January 15, 1914.

Went to state of Washington for J. G. White & Company; been in Denver since May, 1914, with the exception of about a month in the east; since that time has been devoting most of time to his farms in Colorado; bought one farm soon after coming here, another two years later, and two last year; operated them by tenants.

Denver Reservoir Irrigation Company owes him some money, and has been keeping track of its affairs; capital is very largely
809 tied up in irrigated lands, and is interested in the general subject.

When speaking of water supply of the South Platte, in the Denver Reservoir Irrigation Company's territory, had reference to irrigation district No. 2; fairly familiar with the Denver Reservoir Irrigation Company's supply, and had occasion to know a great deal of other ditches during seven years of living here; knows something about district No. 8; Denver Reservoir Irrigation Company takes water from Clear Creek, and right to take it was frequently dependent upon the way the Platte was flowing; the Church ditch was a part of the Denver Reservoir Irrigation company's system; at one time Denver Reservoir Irrigation Company was flirting with English High Line, with the view to purchase that, and the Antero; had an option on the English High Line, and all of its properties; did not result in a deal; has spent a good deal of time in inspecting High Line, and that is the only examination made of anything in district No. 8.

Witness has a general knowledge of conditions in district No. 8; Antero project is in district 23.

One of witness' farms can be irrigated from Marshall lake, or the Standley lake, through the Bull canal; water rights used to irrigate witness' farms under the Standley lake were not stock in the Denver Reservoir Irrigation Company; had other stock and exchanged it to

an irrigation district, and put the lands in the district and the water of the district from the Denver Reservoir Irrigation Company system, and shares in the Farmers Reservoir & Irrigation Company; the two farms under the Farmers High Line were recently acquired; bought the land and water together.

Witness studied the district between Denver and Fort Lupton several times; went through the country from here to Fort Collins, from Fort Collins to Greeley and back through into district 2; made three trips through that territory, and then studied the records of the state engineer's office; spent about ten days or two weeks in studying the South Platte river; trip to Fort Collins and Greeley was separate; spent two or three days at Fort Collins and Greeley; investigation made at request of counsel for defendants; object of the visit was to ascertain what land and water were worth, and what water was selling for; in every case tried to see, and actually did see, some of officers of various companies owning the water; saw people who actually used the water and owned the farms to which it was applied; found out what they had for given amount of land, and what it was worth, based on their belief as to the value of their own stock, or usually on sales that had been made; when hearing of sales, took pains
810 to verify them; not many recent sales had been made, either of land and water, or of water; sales of water alone were more rare than sales of land with water.

Systems visited are all relatively old; would go to banks in towns where the headquarters of the ditches were, to see what values would be placed upon ditch stock as collateral; did not base judgment on what the banker would loan, because bankers are conservative, but their statement of value of stock was usually near to values determined from inquiries elsewhere. One bank in Denver placed a value of $1,250 a share on Farmers High Line stock, and that was the value witness placed upon his own stock; value not based upon what other people said, but upon information considered reliable as to sales actually made; sales usually had been made at less than what stock was selling for five years ago; did not find many sales, but did not mean that no sales were found, or that there were not enough found to give a reasonable amount of information as to what it could be actually sold for; sales made at time similar to the present.

Sales of water alone are rare, and in quantities to supply an average of 80 acres; has not heard of large quantities of water being sold recently, and would expect trouble in selling large quantities; the fact is, not much is changing hands.

Witness had with him Mr. Bull's Exhibit 40, but paid special attention to the use of the water and to what users said about the sufficiency of the supply during recent years.

Witness made a comparison of the assumed Lake Cheesman supply and certain ditch supplies in district 2, based upon Mr. Bull's Exhibit 40, and stated in direct-examination that worth of water right was to be determined by consideration of whether or not the users thereof had sufficient water in quantity, and whether they had it when they needed it. Both of these factors are of vital importance. Plentiful supply in times of lack of need is not as important as plen-

tiful supply at time of need; observed that Mr. Bull's diagram purports to compare with assumed Lake Cheesman supply certain ditch supplies, all on the basis of acre-feet furnished by each ditch compared in each year, and not by quantities furnished in each month; it is likewise true of his tables.

It is quite useless to consider ditch supply without knowing as to distribution of it throughout the irrigation season; it is certainly true that no irrigation supply of water would be a good supply that does not furnish what is wanted when wanted; that is not one of the marked distinctions between storage supply and direct supply, unless it is assumed that the stream is irregular to extent that it cannot supply the water as regularly as the stored supply. There is
811 no difference to farmer in availability or value between water from reservoir or water from streams; just a question of whether either source yields what he wants when he wants it. It is true that any source of supply must be regular or available at the right time, and if a reservoir provided a supply which is more regular, and from which you could get water more regularly when you wanted it than the direct flow, it would be more valuable.

One attempting to draw a conclusion just from Mr. Bull's chart, in Exhibit 40, would be without information as to the supply from month to month. Witness, in drawing his conclusion, applied his knowledge as to the regularity of the supply with reference to the particular ditches compared; did not base his judgment entirely on Mr. Bull's chart; that chart would be insufficient either as to the reservoir or direct supply; not be fair to either of them to draw conclusions without other knowledge as to the actual facts which exist as to when the supply is available.

The South Platte river is extremely variable during the irrigation season. It is also true that the stream flow is seldom low enough but what certain old rights get their water. It is true that for irrigation purposes water is to be applied to the lands in different quantities in different months, depending on many elements—natural rainfall during the month, condition of the soil at the beginning of the month, and need for the coming month, and the crops that are growing, and the necessities. The quantity of water that can be taken through the ditch is a constant one. It is necessary to have a ditch capacity which will supply the highest need for any time during the season. All ditches are constructed on the basis of carrying a certain number of second-feet, in proportion to the acreage. The needs vary from time to time and are controlled by the conditions stated: whether you would need an appropriation and ditch capacity of more second-feet of direct flow than you would have to have of stored water to irrigate the same number of acres, would depend entirely upon the regularity of the stream flow; if the source of supply is regular, would not have to take out and attempt to use any more water than was wanted.

If running stream is level, and one can get water from it when wanted, does not see how it differs from any other source of supply; it would be necessary to have an appropriation which entitles the

user to divert at a rate which will supply the water needed at the time of greatest need.

With a storage right, water could accumulate in a reservoir when not needed, but with an unfailing direct flow it would not be necessary to accumulate it. There is no right to withdraw water except for beneficial use. The judgment of water commissioner is
812 followed on that. When a ditch has no beneficial use, it is shut off. If water is stored in reservoir, it can, of course, be used when wanted.

Whichever source of supply furnishes the more regular supply of water and the quantity that you need at the proper times, is the better supply.

Witness' opinion as to the relative value of the supply from the Brantner ditch, Fulton, Brighton and Farmers Independent ditches, respectively, as compared with the assumed Lake Cheesman supply, was not only on the chart of Mr. Bull, but upon the information which the witness had as to the supply in particular months. That information was acquired in the same way as the information as to the market price, and by examining the state engineer's reports, particularly by knowledge and information as to the actual service of the ditches; less upon inquiry in the engineer's office and more upon knowledge acquired on the ground. Comparison between the ditches and Lake Cheesman was based on the assumption that they were all to be used as a total source of supply; was not considering Cheesman as a supplemental supply.

A market exists for storage water as a supplemental supply; when arriving at the value as a supplemental supply, must consider possibility of its being sold within comparatively short time. Statements made in this case as to value of Lake Cheesman water are on the assumption that the interest and overhead charges would not be very considerable; does not believe it can be sold within a comparatively short time, but is assuming that, and on that assumption assigned the market prices which exist at the present time. Thinks it could have been sold more readily three or four years ago, and very likely at higher prices; thinks they will return; hopes they will be here in five years; does not consider present-day conditions and prices normal; they are either below normal today, or they were above normal a few years ago; perhaps truth is somewheres between; judgment is that the present depression is abnormal; does not think there is a market today to absorb all of Cheesman supply as a supplemental supply; cannot see where either in normal or good times anywhere near all of it could be placed as a supplemental supply; has in mind ditches like the English High Line and the Burlington, which have not now sufficient supply that will enable them to carry through the ordinary farm crops; they may carry through cereals, but a large acreage of alfalfa under them could not be safe; had in mind ditches of that character, which are short now of water to finish off their irrigation seasons; does not recall any other ditches of any importance where that is true.

813 Would confine his judgment to territory between Denver and Fort Lupton; does not know with regard to the supply of

water beyond Greeley, or hardly as far as Greeley; means to include ditches having a sufficient supply for the early part of the season, but that would need water for additional supply during the latter part.

Witness thinks the contracts under the High Line call for 28,000 acres; does not know that the water commissioner's report for 1913 states that there are 90,000 acres physically irrigable from the High Line; as to that ditch, would assume there will be a supplemental supply for 30,000 acres that are drawing water now, and that that amount cannot be materially increased for a yearly supply, and beyond that it would be necessary for them to get another supply.

It has been witness' understanding that English High Line has outstanding contracts which would completely exhaust its present ability to supply, and under that the farmers do not get a sufficient supply.

In referring to Burlington ditch, meant that ditch as extended; it could use water as supplemental to the Barr Lake supply; did not include the O'Brien canal; that is a part of the Standley Lake system; it might receive supplemental water from Cheesman lake, but the Standley lake system has a large amount of unsold water; did not consider the Henrylyn district for the same reason; thinks there is water in the Standley lake system for the Henrylyn district.

A right in the Denver Reservoir Irrigation Company entitles the holder to share in whatever water is furnished for the system, and the right is reserved to sell additional rights up to what is estimated to be working capacity. Purchasers buy so many acre-feet and pro rate on the supply in the reservoir; number of acre-feet that may be finally sold is limited in the contract. The Henrylyn has not an adequate supply; it buys fraction of an acre-foot, and believes they will be in the market to buy water when they find it out; it is a question whether they would buy from the Standley system or some other system, and if from any other system, whether Standley system would permit its delivery.

Henrylyn district is reached by the O'Brien canal and owns proportionate share of the water.

There is a shortage in the Henrylyn district, and when they are in the market to buy, it would be a competition between Cheesman and Standley.

Witness stated that Brantner, Brighton, Fulton and Farmers Independent had all the water that they needed, and believes it to be true. The water that they draw from the stream is not limited
814 by the amount that has been drawn, they can come back and get more, whereas, in the case of a reservoir, they get no more. Shortages occur in the supply of these ditches. Witness says these ditch supplies are better than Lake Cheesman, and bases conclusion upon the fact that during any given season they get a greater supply and are short for only comparatively short periods, which correspond more or less to the periods of shortage from Cheesman; they would have to work with others and perhaps wait a week before ordering water, and then wait two days for it to get down. This year they have fine crops, requiring a great deal of irrigation. The shortages do not seem to occur over such periods of time as to interfere with first-class

irrigation, which is the important point; thinks it is fair to say that these ditch supplies are better than Cheesman, if one assumes that the Cheesman right would be an acre-foot and a half for each acre served, and when that amount is drawn no more can be drawn; means if 50,000 acre-feet were sold and there came a year when the total delivery for the year was thirty or forty, it would reduce for that year the amount which would be delivered.

Examining the chart in Exhibit 40, attention of witness is called to the fact that there are no records for the year 1902 in connection with the Brantner ditch, but knows that stream flows were extremely low and year excessively dry; does not know what supply the Brantner got; attention is called to fact that Lake Cheesman gave over 100 per cent supply that year.

Witness went over the territory covered by Brantner ditch; interviewed persons there; was told that on share of stock in the Brantner represented 11 inches; has not the names of the people interviewed; don't know how many shares there are in the Brantner ditch; does not know whether 11 inches per share is determined by the total decreed priority by the number of outstanding shares; cannot tell the corporate name of the ditch company; does not know whether the original Brantner Ditch Company was a corporation; does not know that it was originally an association of nine persons; never heard that; does not know that the present company is the New Brantner Extension Ditch Company; does not know that outstanding stock is in the New Brantner Ditch Company, nor the number of shares; does not know that the only rights the company has are for water taken under the ditch priority after supplying the needs of the original nine persons; knew it was true of some other ditches. State engineer's report states the amount of water run; they are tabulated in Mr. Bull's Exhibit 40. The engineer's records would include the entire acreage, not only that irrigated by the water of the
815 company, but the water belonging to the old association. If that were true, the water diverted would not represent the water allot-able to the shares of the company; acquired knowledge of the market value of the Brantner ditch shares by conversation with people drawing water and using it; has no personal knowledge of any sale; cannot give the name of any one who informed him of sales; simply gave witness' estimates of market value; don't think that under Brantner ditch any sales have been made recently, especially of ditch stock, separate and apart from the land; none for sale; all applied to the land, and can only be acquired by purchase of land. The ditch has an old priority. Developments have been brought to completion. It would be very unusual to find any stock for sale. It often occurs that the same amount of water can be applied to more land, and that the owner would sell a portion of his water, having more than he needed for his own land. Sales would be limited for lands lying under the ditch, and when all the land under the ditch is covered, the opportunity to sell the water separately is gone, and the market is very much limited.

On direct testimony witness stated that each Brantner share had a market value of $300, represented 11 inches, and divided 300 by 11

to get the value per acre. The information that one inch served an acre was acquired in the same way as the other information regarding the ditch; does not know that the Brantner share does not cover any definite number of inches, but merely a right to participate in the water which can be diverted after the original nine persons have been supplied. The one inch per acre cannot be far from right, when you figure the number of acres and the amount in acre-feet which was diverted for the land; has no other means of arriving at $27.25 per acre than a consideration of the fact that one inch of water is used for each acre; that the ditch draws a specific number of acre-feet, according to the reports of the state engineer; information was that one share waters eleven acres, and it would not make any difference whether there was one inch to the acre or not; the acre price would be the same; got the price per acre-foot by dividing $27.25 by 3.3 acre-feet, which is the amount shown from the water commissioner's reports; doubts whether all the water diverted through the Brantner headgate is applied to the lands under the ditch; knows that water is taken into the head of the Brantner ditch, carried away and turned back into the stream; has no record to show what was spilled out at the lower end; probably much that was spilled out was returned as seepage—that is, water that was applied to the land and flowed back into the ditch. Knows in a general way that water is passed into the ditch and out through the lower end; has not seen the ditch, but believes there is a gate through which the
816 water may be passed out before the lower end of the ditch is reached; unfortunate that in many of these ditches it is impossible to get the actual facts of the water applied on the land. The higher the actual duty of the water, the higher the price per acre-foot.

Witness does not want to be understood as assuming that the price per acre-foot as worked out is correct as to the fair price of an acre-foot of water. To get a fair value, it would be necessary to know what amount of water was actually used. The Brantner decrees aggregate 111.18 second-feet, shown by Exhibit 40; assumes 4,130 acres as the acreage irrigated under the Brantner.

Witness figures to determine length of time the decreed quantity must run to furnish one inch to the acre on the acreage under the Brantner ditch; perhaps all of the decreed priorities must be made use of. All the acreage under the Brantner ditch is practically exhausted, and a purchaser of water under that ditch would have no use for it if he had no land to apply it to. If there is absolutely no sale, can only reach an opinion as to the value of the water rights by comparing them with the water rights sold for equally good land in other districts where there is equally good land and less water; conclusion as to market price on Brantner ditch arrived at from actual sales; generally, the land is all covered; that is true of several ditches in district 2.

Exhibit 44 introduced by Mr. Fellows shows available acreage under Brantner ditch is 5,000; total irrigated in 1913 was 4,560 acres. Mr. Bull's Exhibit 40 shows 4,870 acres irrigated under Brantner in 1911. Practically the only use a purchaser of Brantner water could make of it would be by changing the point of diversion;

if it could be transferred at a profit that would make a market for it; market price would be determined from value of similar water under other ditches. This information obtainable under the Fulton ditch was that one share represented one inch; does not know whether the Fulton is an incorporated company, nor how many shares there are.

It is impossible to state definitely how much each share represents in point of inches of water, except from the statements of owners; knows nothing about it except the statement that share constitutes one inch. One inch will supply one and three-fifths acres. The Brantner has an earlier right and requires more water; acquired knowledge of value of Fulton rights in the same way as Brantner rights; not advised of any actual sales of Fulton stock; took estimates of owners and assumed that was high enough; interviewed perhaps a half dozen users of water and people at the local banks; cannot give the name of a single individual advising value of Fulton sales.

817 Witness repeats method of arriving at the acre-foot value of Fulton water; that value is too low because they use more than is necessary. Does not think too low a price for the shares materially modified the figures, and if correction was made for water taken into the ditch and wasted, that would make a higher value; does not know about outstanding indebtedness of the Fulton. The outstanding debts would have to be pro rated to arrive at fair market price; would not be surprised to know that the Fulton is in the market for supplemental supply. The Brantner and Fulton are near together.

The fact that witness gets $27.25 value for certain Brantner rights and 42.80 for similar Fulton rights is due to fact that the Brantner ditch waters land near the river and takes a larger supply of water than that acquired by the Fulton. Witness is aware that Mr. Bull's Exhibit 40 shows the duty of water in acre-feet is exactly the same in both ditches; it is hard to account for it; controlled to a great extent by local conditions. Witness thinks that all of the land under a certain ditch under irrigation is very important. That is true in the case of the Fulton ditch to a less extent than the Brantner.

Exhibit 44, page 10, table 12, shows that in 1913 there were 10,715 acres irrigated under the Fulton ditch, and 11,000 is the total acreage irrigable.

Further reference to Exhibit 40 shows practical exhaustion of Fulton acreage; does not know whether Farmers Independent ditch is operated by a corporation, or how many shares there are.

Took somebody's statement for fact that each share in Farmers Independent ditch represented eight inches; does not recollect whose statement it was; conclusion that one inch was required for each acre arrived at in same way; interviewed not less than two or three; acquired information as to market value in same way; information as to market value derived from owners; assumed that they knew; owners would often refer to the fact that they bought them for very little; possibly many of them acquired forty years ago and paid for in work, so that they cost just what the labor cost; does not know what one share represents further than statements of owners. Witness explains how he arrived at a value of $9.17 per acre under this

ditch. It is not strange that this amount varies from the Brantner and Fulton values. If the duty expressed in Mr. Bull's exhibit was too low for this ditch, the acre value of the water was too low. If the duty for water for either 1912 or 1913 had been taken, the price would have been proportionately raised. The value arrived at does not represent witness' judgment of value; probably affected
818 and depreciated by the circumstances affecting the other ditches mentioned; did not investigate the question of indebtedness of the Farmers Independent Ditch Company; that will have to be taken into consideration.

As shown by Mr. Bull's Exhibit 40, the actual ditch capacity is 150 second-feet; the decree is 520 second-feet. The first two out of the three decreed priorities are all that this ditch will take care of. Reference to Mr. Bull's Exhibit 44 shows that this ditch cannot at all times secure the quantity decreed to it under the first two priorities.

The supply of this ditch for the year 1913 was such that it would not yield water for late irrigation. When shown the performance of the Brantner ditch in Exhibit 44, table No. 11, which showed fifty per cent more in June than in September or May, less in July, less in August than in June, witness states that the desirability of such a rate of supply would depend upon crops that are growing, and just what use one wishes to make of it. There is sufficient water in August and September to supply a fair proportion of the acreage and the crops needing water. All cereals would have been harvested before that time.

Referring to the Fulton ditch, table shows that large part of the supply is furnished in the month of June; that it falls off in July and August; thinks that is a satisfactory rate. Cereals would be finished by that time. Sugar beets, potatoes, and crops of that sort, or alfalfa, would need an evener and larger supply, but farmer is not apt to have more than half of his farm in crops which require water after the first day of July.

Whether the Cheesman supply would be better would depend upon the amount he was entitled to receive. If a farmer had bought only an acre-foot for each acre of land, he might not be able to get a better distribution than that shown by the ditches; he would have to order it when others were using it; will not modify views as to the superiority of ditch supply. It is a mistaken impression to think that water can be gotten from a reservoir exactly when needed. The supply is limited by the quantity purchased, and can only be gotten when other people are running.

Witness put no price on rights in Brighton ditch, because could get no market value on the shares, water not being sold separate from the land; could find no cases of sales. As to other ditches mentioned, would say there had been water sold or offered for sale under them; such sales did not cover any considerable quantity, usually not exceeding 80 acres.

819 Farmers High Line Canal and Reservoir Company takes water from Clear Creek; one share represents ten inches; cannot tell how many shares there are; reached that conclusion by knowledge of his own ownership; cannot say what the shares represent,

except that it is treated on the basis of one share, representing ten inches of water.

Witness owns one share for each 35 acres irrigated; that is his only source of supply; has some small reservoirs in which that water is conserved; this equals one inch for each three and one-half acres; higher duty of water than in case of other ditches; has had shares offered at $1,250 per share within three or six months.

There are no considerable number of shares for sale apart from the land. Shares entitle owners to participate in small reservoir capacity. Witness bought his land, water right and reservoir together, and thinks that deducting the cost of improvements, including the reservoirs and the price of the land, the shares cost less than $1,250. Perhaps half of the users under the system have private reservoirs; should not want to depend on one share to irrigate 35 acres for the growing of beets and potatoes, and crops of that sort. To get the very best service out of the water the private reservoirs are desirable.

Company has outstanding indebtedness; does not know the amount. Whether the indebtedness should be added to the market price of the shares, in order to get the value of the water, would depend upon whether there was any treasury stock to be sold to pay indebtedness; does not know whether there is any treasury stock in the company; has three small reservoirs on farms, aggregating 140 acres; thinks it cost $500 to construct the reservoirs; would be about $3.50 an acre. Arrived at $28.56 per acre-foot on basis as explained in direct testimony; is well operated ditch; the needed amount is less and the water is thoroughly conserved and used.

There is plenty of land that the canal can reach, but assuming that stock had been issued, representing all of the right to divert and use the water, then the amount not in use would represent the amount which could be put into use. There is a great deal of land on which water could be applied; it would require additional construction. The lower end of the ditch reaches the Brantner ditch territory, but the unwatered lands it is proposed to serve by the Standley lake system.

Difference in value between the Brantner value of $300 for 11 inches and the Farmers High Line of $1,250 for 10 inches is hard to account for. Two parcels of land equally well located are sometimes of different market value. The difference in value be-
820 tween these two water rights may depend on the fact that the lands under the Brantner and other ditches are pretty well served, and there is a great difference in the two areas of land; thinks the strongest reason for the difference is that under the Brantner and Fulton all the land that can be reached by the ditch is under irrigation.

There has been considerable reservoir development in the Poudre district; has not valued stored water there separate from other supply. The Cache la Poudre systems testified to by witness are supplied by combination of direct rights and reservoir rights; testimony here covered market price of the combination of rights; in one or two cases they were separated. In Larimer & Weld canal system

one share represents 1.44 second-feet; that allows participation in direct flow entirely; does not know whether Larimer & Weld system is a corporation. Was informed by the superintendent of the ditch and others that one share represented 1.44 second-feet; assumes that that is reached by dividing total quantity specified in the decrees by the number of shares; does not mean that each share is entitled to constant flow of 1.44 scond-feet, and gets it, but means that each share is entitled to a ratable proportion of the entire product of the direct-flow rights of that company, not to exceed a rate of flow of 1.44 second-feet; market value $4000 per share; was told that there was delivered annually under direct-flow rights 105 acre-feet per share; superintendent said during the first twenty days of irrigation season there was a half supply; next twenty days a full supply, and for the remaining ten days of the period of fifty days got a half supply; probably began May 1 to 15; run would end about July 1. Considered a fair supply without supplement for cereal crops; must have an additional supply for alfalfa and sugar beets; that comes from storage. Reservoir water is worth $2000 per share, or $4000 for 160 acres; does not know whether Terry Lake is owned by separate corporation; does not know anything about the capacity of the reservoir or of the number of shares sold; only knows that this reservoir supply is used as a supplement after the direct supply has been run.

The 1.44 second-feet of the Larimer & Weld canal is supposed to furnish sufficient supply for 160 acres during the fifty-day run.

If witness should be mistaken, and the Larimer & Weld canal right, calling for 1.44 second-feet, is a right for 80 acres, it would raise the acre value. The direct-flow right gives 105 acre-feet for each share; got this information from the superintendent; does not know what the duty of the combined supply is.

821 Various farmers believe the duty in the Cache la Poudre district to be from 1¼ to 1½ acre-feet for each acre served; did not study that phase of it. The water-right value under the system is approximately $50; cannot tell what is the value per acre-foot of the storage water; reservoir rights purchased and paid for separately and represented by different stock; does not know whether they carry any proportionate cost of these ditches through which the water is carried.

The direct-flow prices do not necessarily cover the distribution ditches, if both direct-flow and storage rights are bought jointly; presumes the reservoir adjuncts were created after the direct-flow ditches were built. It is quite impossible to grow beets, potatoes, and those crops, without a late supply of water; such crops are raised successfully in the Cache la Poudre district, about Fort Collins and Greeley; they raise a considerable acreage of crops of that character under certain parts of the High Line, and all along the Platte.

In view of the high duty of water in the Poudre country, witness accounts for the low duty of water in other districts mentioned by the fact that land in the latter districts requires more, and the conditions covered by other answers; possibly unnecessary diversions and drawing of more water than is needed. Water Supply and

Storage Company's system, one share sufficient for 80 acres, originally intended for 40 acres, supplemented with storage facilities; has no knowledge as to its priority; did not inquire into it; only knows that it is said that in conjunction with the direct supply, it is sufficient; does not know character, size or yield of the reservoir, or how many shares are outstanding, or what one share represents, by process of arithmetic, nor what portion of supply is furnished from storage; does not know acre-foot amount supplied from either source; ascertained market price to be $300 each, from inquiry; did not find any considerable changes in ownership; did not attempt to find out the number of shares that had been sold; knows nothing about outstanding indebtedness; that must be considered.

Larimer County canal No. 2, commonly known as the Cache la Poudre canal; cannot tell where the intake is; got the information concerning it from Mr. Nelson, superintendent of the Greeley Water Works; one share sufficient for 40 acres; shares represent both direct flow and storage; is not able to state of what the storage supply consists; storage water used at the close of the season; cannot say how much total supply is furnished by the direct supply, and how much by storage; does not know duty under the system; cannot
822 state what is paid for storage and what for direct flow. For combined supply the price is $50 for each acre served.

Information not confined to one source only; headgate is about half mile from the town of La Porte; does not know where the reservoirs are located; lands irrigated are in the neighborhood of La Porte.

Witness crossed canal and drove over the lands. The information concerning Consolidated Hillsboro ditch was obtained at Greeley; did not see the ditch or any land lying under it; does not know where it take- its water; all witness knows is what someone told him at Greeley; was told one share of stock represents 50 inches; does not know how informant arrived at that conclusion; was informed that one share of stock furnished supply for 80 acres; information is that it diverts water from the Big Thompson, being decree No. 1; thinks it is purely a direct flow; by reason of its early priority, sufficient to furnish a supply for entire season; means the first decree out of the Big Thompson; ditch has later decrees, but does not know the amount; does not know the date of the earliest decree.

Does not know how many shares of stock there are in the ditch, or what its decreed priorities are; has no knowledge or information upon which to base independent judgment as to whether or not the purchase of one share was enough to adequately irrigate 80 acres; does not know the duty of water under system; market value at present time, $1800; information derived from same source; does not know how many shares were sold at that price; knows of no specific sales; has sold as high as $3000 per share; knows nothing beyond what he learned from his informant; knows nothing of the circumstances of the sales.

On $3000 basis, acreage price would be $37.50 instead of $22.50; knows practically nothing about the Home Supply ditch; has no

knowledge about reservoir supply for it; former computation was wrong. A right consisting of ten shares is sufficient for 80 acres; cost per acre would be $50; wishes to so correct direct testimony; never saw the ditch or the land under it; information from P. W. Allen, of Greeley; does not know how much water is furnished to the owner of ten shares, or whether it is direct or measured supply; knows nothing of the date of the decrees or the quantity of decrees, or the duty under the ditch, or whether it takes water from the Cache la Poudre or is located in district 3.

Did not investigate the duty of water in the Cache la Poudre district; did not investigate what proportion of supply came
823 from reservoirs and what was direct; did not learn the market price per acre-foot:

Witness returns to Burlington ditch; does not know how many shares there are in the total of its decreed priorities.

All sales of water, of all kinds, under all provisions, are subject to the proviso that the stock participates, if the source of supply is available; Burlington decree is known as a late decree; the ditch's supply is uncertain and irregular in quantity; is ditch of considerable variation; knows this from observation; very unsatisfactory supply; marked value of Burlington stock, $100 per share; placed that value on the shares because ten shares were offered to witness at that price; does not know whether there is a considerable amount for sale; thinks the only available data would fix the value of the stock; knows of no considerable sales.

It was the general opinion of those who used the water that that was the value of the shares; talked with half a dozen; witness explains method of arriving at acre value of the water. The duty of two acre-feet per acre was arrived at by data from water commissioners, which includes all diversions; did not know that these diversions included storage diversions.

Witness was referred to his testimony on page 2895 to the effect that his investigations under the Burlington were confined to lands this side of the Oasis reservoir. In explanation of it, witness said: "The investigations could not have included that; as a matter of fact, I did not know whether the general average of 2.2 feet included the storage supply and also included the water which was delivered beyond Barr lake, or whether they would get the benefit of the storage supply; I suppose the figures do relate to the entire district, the entire area under the ditch, but my own immediate investigation and statement at that time referred to the examination which I recently made."

If storage diversions were included in the basis for computation of the duty of water, correction should be made, and the cost per acre would be correspondingly greater; does not think this value on Burlington water should be used as a criterion. The Burlington ditch is better in some years and the Cheesman supply is better in others.

Does not think that the Burlington ditch has a better supply than Lake Cheesman; has stated that the Brantner and Brighton are better than the Cheesman, and is not sure but what the same is true of the

Fulton. To determine that, it was necessary to know what the ditches were getting from month to month, and witness did this largely from observation and by study from Mr. Bull's tables
824 in another exhibit. If at any time, a ditch having a junior right was drawing water, and the Brantner was not drawing all to which it was entitled by its decrees, then it would be assumed that the Brantner was getting all it wanted.

In order to say that a ditch supply is better than the Cheesman supply, it must appear that the ditch user can get all the water he needs in any particular month of the irrigation season, and that he cannot do so from the Cheesman supply. There are years in which the chart would seem to indicate that a user could not get what he needed from Cheesman on the assumed draft of 60,000 acre-feet: that would be because of shortage of supply in particular years.

The ditch systems described in the Poudre district are completely developed; does not know whether the lands in that district are all supplied or whether there is any restriction of the market for the water. If all the acres physically under the ditches are now supplied with water, it would limit the amount to which additional water could be sold and practically destroy any market, unless for purposes of transfer. Transfer is exceedingly doubtful and very expensive. These considerations would depress the market price of such shares; would not apply the acre-foot value applied to the ditches in district 2 to the Cheesman supply; would not use it as a definite guide; it would be a factor. The accuracy of conclusions arrived at in respect to the ditches is subject to various considerations; they are all direct-flow ditches.

As to the Poudre systems, did not ascertain the value per acre-foot or the duty of water; did not attempt to arrive at a guide as to cost or value of water per acre-foot, particularly as to the cost or value of stored water per acre-foot; only experience in Colorado and in vicinity of Denver in respect to actual sale of stored water is in connection with the Denver Reservoir Irrigation Company: had something to do with first effort to sell D. R. I. water to farmers, at a time when system had not been constructed.

Standley lake is the backbone of the Denver Reservoir Irrigation system; cannot say how many shares were offered for sale in 1907 to 1909. The amount was increased from time to time with the addition of other systems. There was always a limit to the amount of capacity which could be sold.

There was always an agreement as to the extent to which the stock could be diluted. There were a number of sales made in 1907. As the capacity was increased, and more systems added, a greater amount of stock could be sold. Original purchasers expected to get
825 their water supply from system as a whole. Work was being done on Standley, but was not completed.

Purchasers at that time would have to rely for a supply upon a system, an important part of which was merely in process of construction, and would be expected to pay for his stock or mortgage property to secure the purchase price. The limit of sales that could be made was fixed; experience has been that while the work is being

actually prosecuted and laborers are building ditches and dams, you can get as good results on sales as you can later, when there is not that live phase to appeal to the purchaser.

Witness would prefer to buy from a completed system, but as a matter of fact, in selling, the early stage of construction is a psychological time to sell; does not think that a farmer buying under those conditions is using good judgment, but is frequently done.

Denver Reservoir Irrigation shares were offered in 1907 and 1908 at $500 per share, representing right to 10 acre-feet, or that proportion of the water actually stored which ten acre-feet bore to the entire capacity. There was no guarantee that 10 acre-feet would be secured; it was represented that in an average year each share would get ten acre-feet; that occasionally it would be below, and at other times higher. The shares were limited to ten acre-feet, but the representation was that the remaining unsold water would be distributed so far as safety would permit to those holding shares. Does not recollect how many shares were sold; does not know what the total yield was to be; a very good efficiency was assumed; that would in no year fall enough below to be outside of good business. The efficiency of 90 to 100 per cent is good, provided there are not any or a very few years when it gets below 60.

Witness was for two years manager of the Denver Reservoir Irrigation Company; does not know what efficiency was calculated; was responsible for care of all the lands and the distribution of water when available. There was a general manager responsible for the other phases. The sale of water rights was not directly under witness' control; was a member of the executive committee, in which all these matters were discussed, but actual carrying out of the sales did not come under his jurisdiction.

Does not know what representations as to efficiency were made. Sale to the Henrylyn was made in 1910 and 1911. The completion of that sale was made at the close of witness' receivership; recollects 5,000 shares, representing 10 acre-feet each, were sold to the Henrylyn; cannot say how much of that would be supplied by
826 direct flow and how much by storage; Standley lake water taken from Clear Creek, fed by the Croke canal; it is a rather late priority, later than Cheesman; Standley is not decreed; cannot give the total storage capacity of the Standley system; understanding is that it is believed to be substantially 60,000 acre-feet for Standley lake; this is larger than Milton lake. The original Barr lake does not belong to Standley system; the enlargement does; the supply for the Henrylyn district must come from Standley lake, including the 50,000 acre-feet sold to the Henrylyn district. Cannot say how much has been sold out of Standley lake.

Unsold stock referred to on direct-examination was stock in the hands of the trustees who had charge of the Denver Reservoir Irrigation Company business; thinks 210,000 acre-feet ought to be sold, and that Standley capacity represents half the system—that is, with 125,000 acre-feet of reservoir capacity, 210,000 acre-feet of water will be sold. Did not intend to say that all of the water supplied would come from storage. There would be direct-flow rights passed

through Standley lake; there is a considerable amount of water available for direct flow from Clear Creek; also water available from Marshall lake, and from the O'Brien canal.

The direct flow from Clear Creek would be recent. The Marshall lake direct flow is a relatively new right and small in quantity; would not be surprised if the sale to Henrylyn was 75,000 acre-feet.

A purchaser of shares in the Denver Reservoir Irrigation Company gets a right to share proportionately in all the sources of supply of that company, which has a reservoir capacity of 120,000 to 125,000 acre-feet, with the understanding that the company reserves the right to sell 210,000 acre-feet, modified by the consideration that it is intended to build Standley to a 90,000 acre-foot capacity; there is no guarantee. The sale to Henrylyn was made at the price of $500 per share, or $50 per acre-foot; that includes a share in all of the diversion works, canals, and so forth.

Standley lake differs from Cheesman lake, in that Cheesman is a stream-bed reservoir, and Standley lake takes its supply through a canal, and Standley has to deliver through ditches and structures into the Platte river; Cheesman delivers into the Platte river direct. Henrylyn acquires a proportionate interest in the O'Brien canal, but does not know what that interest was.

Witness understands that if Henrylyn district wanted Cheesman water, Standley system might refuse to carry it. So far as witness knows, the Henrylyn people acquired the right to have their water carried through the O'Brien canal from the Platte river to the boundary of the district.

827 Impossible to say what part of the $50 acre-foot purchase price applies to the structure; has not clearly in mind whether the distribution canals in the Henrylyn district were built by the district or not. Cannot tell what part of the purchase price of $50 per acre-foot should be apportioned to the cost of the Henrylyn district's interest in the O'Brien canal.

When asked to justify the price of $35 per acre-foot of Cheesman, as compared with $50 for the Denver Reservoir Irrigation Company, witness says that the Henrylyn water was paid for in bonds, and the bonds had to be discounted. Witness believed that the bonds were worth their face, but it is not turning out so. The 1907 sales were not cash sales.

Estimates of the probable yield of Standley lake would not be as accurate as the estimates of the probable yield of Lake Cheesman.

The land lying under a system always limits the possibilities of sale. Cheesman reservoir has greater possibilities of sales than Standley, and a consequent wider market.

Purchasers of Denver Reservoir Irrigation shares have not paid in cash, and they are being carried, and many are past due. The price assigned to Lake Cheesman is assumed to be spot cash.

The values assigned to Lake Cheesman and Lake Marston are strictly for irrigation; does not undertake to say what would be the value of those reservoirs for use in connection with supplying the city and county of Denver and its inhabitants with water for do-

mestic and city uses; would think its value would be much greater than for irrigation purposes.

Redirect examination by Mr. Nye:

Report made for J. G. White and Company on Denver-Reservoir Irrigation Company system in 1907 had to do with location and availability of land which it was proposed to water and prices they would probably bring when watered; involved no engineering features; inquiry was limited in time and to specific things; something like 30,000 acres are now watered under the High Line; the remainder of the 90,000 acres mentioned by witness has not been watered, and the water from Cheesman could only be applied to 30,000 acres as supplemental supply.

If Cheesman water was used for the larger acreage it would be a full supply as to part thereof. Referring to diagram on Exhibit 40, comparing Cheesman supply on a 60,000 acre-foot draft and the Brantner supply, it appears that while Cheesman supply would have been 100 percent efficient in 1902, a shortage of water in the stream in that year is seriously reflected in the available reservoir supply for 1903.

828 Witness thinks page 9 of exhibit 44 shows that the Brantner and Fulton ditches were getting an adequate supply in a normal way in the year 1913. As to the Home Supply ditch, there are ten shares to the right, one share for 8 acres, 80 shares for a right.

The available water of The Denver-Reservoir Irrigation Company at the time of sale of rights in 1907 and 1909 was through the Church ditch and Community System; first sales of Denver-Reservoir Irrigation Company water were on the following basis: A contract was made between the company and the purchaser, which was in effect a promissory note, for $50 per acre-foot, or $500 a share; the time for first payment of interest was not to commence until work had progressed to some certain stage, and after signature to agreement the purchaser executed a mortgage upon the land, to which the water was to be applied; no cash payments were made; these contracts and mortgages were deposited with the trustee in Chicago, and against them the bonds of The Denver Reservoir Irrigation Company were issued, and these bonds were then sold by a bond house. (Plaintiff objected to testimony as to the price at which bond house sold the bonds, which objection was overruled.)

Bonds sold at 80 to 85 cents on the dollar.

It was at first attempted to sell the water on the basis of a delivery at the outlet of the reservoir, but none were sold under those terms; some were actually sold under provision that the company was to construct main canals, which it did, and also constructed the branches; the delivery was then at the headgate of the canal under which the water was to be used.

The difference in value between the Cheesman Lake and Marston supply on one hand and The Denver Reservoir Irrigation Company supply on the other, would be that the latter company have built a very extensive distribution system at a cost of not less than $15 per acre of land served.

Recross-examination by Mr. Dorsey:

The obligation assumed by The Denver Reservoir Irrigation Company for delivery on east side of the Platte was to deliver at the headgate on the east side of the Platte; the quantity delivered was to be that proportion of the water in the reservoir which the users' shares bore to the total shares issued; measurement to be made at the intake of the canal.

Witness is not sure what interest purchaser acquired in the reservoir. As for the intake to The Denver-Reservoir Irrigation Company reservoirs, the reservoirs themselves and the outlets, in comparison with Cheesman Lake, Cheesman Lake is both intake,
829 reservoir and outlet. The sale of sixty-five or seventy-five thousand acre-feet was the largest and the last sale made.

In estimating the value of Cheesman water, witness considered that perhaps 25 per cent of it would be sold to the High Line as supplemental water; perhaps the supplemental water would be worth more and perhaps less; did not intend to limit valuation to a consideration of High Line supply; value fixed was assumed to be net selling price; did not intend to deduct overhead cost and expense of making the sale; started with an assumption of $50 for a sufficient supply for the land; could not think of Cheesman's total supply being used as supplemental water; would say that if it could be so used, it would bring more. Witness knows more about soil, its fertility, productivity and the character of crops, than about other phases of farming. Witness' reports have been generally directed to that point; has had to examine reports on the sufficiency of water supply, value and kindred questions, and pass upon them.

On two or three occasions has assumed that reports on such questions have been true, and had occasion to regret it. In a good many of the J. G. White reports, has had to go deeply into the subject; could not say that years of drought and years of plenty follow one another in any orderly succession; according to the doctrine of probability, there is less probability that a year of dry flow will be followed by another similar year.

FREDERIC W. TAYLOR, witness for defendants, resumed.

Redirect examination by Mr. Nye:

Finds in the office of the state engineer certified copy of a decree entered in Boulder county December 19, 1901, in case of The Farmers Irrigation Ditch Company vs. The Consolidated Hillsboro Ditch, wherein occurs a provision reciting that the Big Thompson Canal No. 1 has priority No. 1 on Big Thompson river, dating from November 10, 1861, for 96.5 cubic feet per second, and that the Consolidated Hillsboro Ditch owns 4/14 thereof. That ditch is said to be using that amount of the first priority.

Recross-examination by Mr. Dorsey:

Does not know what proportion of the entire Consolidated Hillsboro decrees and priority the No. 1 water makes up.

830 ANDREW M. PATTEN, a witness for defendants.

Direct examination by Mr. Nye:

Has been connected with the Union Central Life Insurance Company of Cincinnati for seven or eight years, and is now taking care of certain loans for them; duties have been to pass on farm loan applications for it; has lived in Colorado 26 years; was county commissioner of Adams county for four years; is familiar with every irrigated district in the state; is familiar with the irrigation systems along the valley of the Platte, through interest in certain water rights and as representative of the insurance company; has had to examine practically all the essential ditches between Denver and Greeley, and investigated their value, by getting the amount of water required by a farmer and the efficiency of the same, and then consulting records in the state engineer's office, visiting both owners, farmers and available records; is interested in corporations that own lands under the Farmers High Line and the Standley system; has investigated northern beet fields from Boulder to Greeley, in the Arkansas Valley; has had extensive acquaintance with the territory in general; has kept generally advised of land and water values in the district in question, and has recently made special investigation of water rights from Denver to Platteville, and the tributary streams of the Big Thompson, Poudre and others; has made inquiry from people using the water, both land owners and tenants, as well as the officers of the ditches; through tenant, is now farming irrigated land; has farmed land for others; was at one time interested in land under Marshall Lake, some land irrigated under Farmers' High Line, some under Standley system, also interested in holdings that are irrigated from the Poudre Canal and Reservoir Company; that land is within a radius of seven miles from Wellington, north of Fort Collins; is familiar with the Brantner ditch, Fulton and Farmers Independent, which he has recently investigated; previously, had a good knowledge of all of them; some are very hard to get information about.

In years past has repeatedly tried to get information concerning them, with no success. Recent investigation was made as a personal investigation from the owners of the land, to try to confirm, if possible, witness' own conclusion; knows the market value of land and water under the ditches mentioned; also investigated the Burlington ditch.

(Plaintiff objects to witness testifying as to the value of water for an acre under Brantner ditch. Overruled.) Water for Brantner ditch is selling for $300 per share, when selling; a share consists of 11 inches of water; this would be $27.25 per acre.

831 The market value per acre of water under the Fulton ditch would be $42.80; an inch is supposed to water one and three-fifths acres; one inch per acre is required under the Farmers Independent; the present shares call for 8 inches; values them at $300, or $27.50 per share; could get no information on the Brighton ditch, but thinks it would be governed by the Brantner, which is a parallel ditch; has no other way of telling the value.

The market value of shares of the Burlington ditch is $100 for four inches. Four years ago paid $130 a share for some, but is

now offered 8 shares at $90 a share; these shares carry one inch per acre.

Market value of water per acre served would be $25; shares under the Farmers High Line are worth $1,250.00 per share, 10 inches to the share, one share will water 30 to 35 acres; the efficiency of this water stock is increased by private reservoirs, by the use of which five shares is considered a good right for 160 acres; the market value per acre of land served is $35.70.

Farmers High Line supply is a good and sufficient supply for the land. The East Lake Water Company has direct and stored supply. The direct supply from the Farmers High Line is worth $35.70 per share and runs one and one-fourth acre-feet per share per season. The reservoir capacity is well worth $30 for three-quarters of an acre-foot, and the two combined into a water right would be $65.70 for a two acre-foot right, and would supply around two acre-feet to the acre; that would make $32.85 per acre-foot delivered on the land. In fixing value of water of the ditches testified to, considers water delivered at the headgate. Witness has had general knowledge of all ditches in the Poudre district testified to by Mr. Taylor, and has made a recent investigation, at which made personal inquiry of users of water under various ditches, and of officers of the company and owners of water stock; aimed to ascertain actual market value of the water; investigations surprisingly confirmed previous opinions. Under the Larimer and Weld County ditch, one share represents 1.44 second-feet, market value of which is $4,000; supplemental supply from Terry Lake and other reservoirs; one share of direct flow and two shares of storage rights serve 160 acres; total market value $8,000; $50 per acre of land served. Has a notation of sales of water stock in 1911 for $4,500 or $4,600, but present inquiry shows that direct-flow shares are selling at $4,000; supply is good and sufficient.

Witness' East Lake property is located on Union Pacific 14 miles north; small settlement there. Union Central Life Insurance Company has close to two and one-half millions in farm loans
832 throughout the state; witness' office handles them all; makes nothing but farm loans.

Is familiar with the Larimer county canal; one share supplies 80 acres, shares selling for $3,000; has notation of a sale in 1910 for $3,750; present market value is $3,000; $37.50 per acre of land served, includes good reservoirs; delivers a sufficient amount of water for lands on which used.

Larimer County Canal No. 2 Irrigation Company supply, part direct flow and part storage; officially known as the Cache la Poudre canal; value, $50 per acre of land served; one share for forty acres.

Consolidated Hillsboro, one share represents 50 inches for 80 acres; market value $1,800, direct supply; the highest value at which these shares have been sold $3,000; at $1,800 it would be $22.50 per acre of land; at $3,000 it would be $37.50 per acre; the present value is $1,800 per share.

Consolidated Home Supply ditch, one share represents 10 acres; market value $400; stock sold in December, 1912, at $450; shares sold in the spring of 1906 at $500, which would be $40 per acre of land served. Hypothetical question put to witness and asked to tes-

tify as to market value of Cheesman and Marston lake rights, objected to and overruled.

Thinks the assumed Marston Lake Supply and the assumed Cheesman supply on a 60,000-acre foot draft would be worth $45 to $50 per acre-foot at the headgate of the ditch using it; worth less at the reservoir, in proportion to the seepage, percolation and losses; that would be net price to owner, he to assume a reasonable maintenance charge upon the ditch that he conducts; water would be worth $45 to $50 to the consumer.

Value to the seller would be that price less cost of selling and loss, and interest on the investment; would not include maintenance charges, but would include overhead charges. Marston lake water might not be quite as valuable, as the possible market for it would be very limited; for example, could not deliver to the English High Line.

Does not think market for Marston and Cheesman water could be found to absorb it all as a supplemental supply, without a considerable delay, if at all. At $50 per acre-foot, witness considered it as a supplemental supply for ditches already constructed; would not be as valuable as an original and sole supply, because the lands to which it would be applied would not be as valuable or as well located, and would be raw, and the expense of constructing ditches and laterals would be greater; estimates water would be worth $15 per acre less for sole supply.

833 Cross-examination by Mr. Dorsey:

Prior to association with insurance compan,, witness' business was farming irrigated lands; has not been engaged in the business of buying and selling water rights, but has been engaged in constructing ditches and reservoirs; never connected with the sale of water rights separate from the land; is in the business of selling lands and water rights together all the time; was interested in the old Denver Land Company and in another company outside of Colorado; would qualify by saying that to some little extent has sold water rights separate from land, one purchase amounting to $17,000; bought for the purpose of speculation and resale; witness used some of them on his own lands; has speculated somewhat in water rights under the Burlington.

In some instances knowledge of sales of water rights in Poudre and Big Thompson districts was derived from what others say, in some instances not; familiarity covering a period of seven or eight years; although owning lands under the Poudre Canal and Reservoir Company's system, is not well posted on it and does not testify to it. Recent investigations of Brantner, Brighton, Fulton and Farmers Independent and Burlington resulted in information different somewhat from former impressions. As to the Brantner and Brighton ditches, lands possible of irrigation thereunder are now irrigated, but not true as to Fulton, Farmers Independent or Burlington.

There is a new High Line-Fulton ditch having a flood-water right, that could be bettered by the use of Fulton stock.

The market for shares under the Platte ditches mentioned is exceedingly limited, if one excepts the Burlington, and possibly the Farmers Independent, and to some extent the Fulton; this fact has

a marked influence upon the market value; knows nothing about the corporate organization of the Brantner; is not aware that the Brantner was built and originally owned by an association of nine persons.

The amount of land irrigated under the Brantner is limited, and there is not a possibility of applying this water on newer lands, but more intensive cultivation of the present lands may require more water, and that is about the only market that would open up; knows it as a very early ditch, a very good ditch, and that it supplies all the water that the farmers under it seem to require. The term "one inch" refers to the statutory inch which signifies a rate of flow.

One share of Brantner stock receives at the rate of 11 inches per share, fluctuating with the supply of the ditch; has never used water under it; possibly witness' informants meant that each share of the Brantner ditch entitled the owner to a proportion of the total yield of the ditch that his shares bear to the total outstanding
834 shares; market price of $300 per share was confirmed by inquiries of land owners and officers of the ditch, undoubtedly based upon the last sales made.

There has been very little changed hands; the low price of the Brantner ditch rights per acre, as compared with the later rights of the Fulton, Farmers Independent and Burlington, is not remarkable, when the possibility of market for them is considered. Thinks that the comparison of value is somewhat along proper lines of valuations of the amount of land which would create the market. Under the Brantner, practically every acre is in a high state of cultivation; under the other ditches mentioned, water is taken farther away from the river, and there is a greater market. The purchaser of a share in the Fulton ditch acquires one inch; does not mean that the purchaser gets an inch, but he must take that proportionate part of the total supply as compared to the total shares. Thinks there are 20,000 shares; does not know whether they are all unused. Does not think there is any considerable quantity of floating stock under the Fulton; does not know whether it is all issued and used; got information as to market value of Fulton shares in the same way as others; has information that in 1906 Fulton shares sold at $100 per share; was not informed of any other sale; from observation, would say that one share is sufficient to irrigate one and three-fifths acres; by applying one and three-fifths acres for each share, arrived at market value of $42.80 per acre.

The present appears to be a period of depression in the value of water stock; witness thinks it will last for a couple of years, and then improve. Does not think the present price is normal. Only knowledge of sales in Fulton ditch was a sale at $100 per share; was not informed of any recent sales at $65 and $75 an acre; does not know the circumstances of the $100 sale.

The amount of water obtainable on the shares would fluctuate with the number of shares in use at a particular time and with the available water in the stream; is not informed that 3.3 acre-feet per share is the yield of the stock for the number of acre-feet actually delivered. Can only state as to the amount of flow maintained in the ditch and

the months in which it occurred, from observation; has never conducted operations under the Fulton; it was incorporated for 2,770 shares, par value $20,000; all the land under the ditch is actually irrigated, and it restricts the market, but not to the extent of the ditches on the other side of the river, because there is a larger area and more people served.

Referring to Exhibit 44, page 12, where the acreage of the Fulton ditch is reported as 11,000 possible and 10,795 actually irri-
835 gated, witness states that that conforms to his understanding, so there would be but a small number of additional acres to which Fulton water could be applied, unless it would be possible that the Fulton High Line can utilize it; does not mean to say definitely as to that, but has the impression that it can be done.

Knows that a number of ditches having excessive decrees have enlarged their capacity and extended their ditches and used the water upon new land, and thereby acquired the right. Only gave limited consideration to so-called Fulton-High Line ditch; additional market more likely to be brought about by transfer from certain present owners to others who intensify their cultivation; does not know what acreage the Fulton-High Line brings under irrigation. The assumed added market for the Fulton ditch water would be very limited; no storage supply under either Fulton or Brantner; has never operated the Farmers Independnt ditch, but has operated farms under it; has a few farm loans under the ditch.

Arrived at the estimate of 8 inches per share from personal knowledge and information. The Fulton ditch supply of one inch to one and three-fifths acres is adequate; knows that the owners of shares under the Fulton ditch have been looking for storage water. Knows that the Farmers Independent has an aggregate decree of 526 second-feet, and knows that the ditch capacity is limited to the amount of the decree; thinks that Mr. Bull's Exhibit 40, showing capacity of the ditch to be 150 second-feet is right; if conclusion that one share represents 8 inches is arrived at by dividing the decree by the number of shares outstanding, the result would be incorrect. Information regarding Farmers Independent is difficult to get. It was originally incorporated with a value of $1600 or $1800 per foot; is sure at the present time one share representing 8 inches is worth $300; does not know how the 8 inches is arrived at. One inch is sufficient for an acre; has no knowledge of sales at that price; was not informed of any particular sale; has arrived at a value of $37.50 per acre by dividing the market price of $300 per share by the 8 inches.

There is a considerable amount under the Farmers Independent Ditch which might yet be irrigated, but it is questionable how desirable it is. Exhibit 44, table 12, giving the acreage under the Farmers Independent, and Exhibit 40, showing the actual irrigation thereunder, indicate that the total acreage is served and the market is restricted; there is no reservoir supply.

Could get no reliable information on the Brantner; all land under the ditch is irrigated, with consequent limitation of market; market

might be created by intensive farming on part of the lands;
836 not able to establish any market price for the Brantner water; arrived at the representation of the Burlington shares from general information.

Divided the total quantity of the Burlington decree, expressed in inches, by the number of shares, and arrived at the result of four inches per share, which might fluctuate with the number of shares in use, as well as the run of the water in the ditch.

Four thousand shares in the Burlington ditch; believes it will deliver four inches per share, but not running continuously throughout the irrigation season; does not think the ditch is a fair comparison; it has been to a certain extent a flood-water ditch; has seen water running in the ditch during the winter months and distributed on the land, as a sort of storage; some intensive farming near Henderson covered by this ditch.

All things considered, they get very effective use of the Burlington right; the ditch's decree is very late for direct diversion; there has been a great irregularity in total quantities. The market value of $100 per share is arrived at by actual personal knowledge and purchase of the shares; personal transactions occurred about four years ago; witness bought four shares at $130, which was the high market price; has offered the same shares at $100; has a quotation of $130 per share in the year 1911; has no other personal knowledge of sales of those shares; shares have never been used since witness bought them.

Same parties who sold witness his shares recently offered 10 shares at $90 per share, or one share for $100; this was Mr. Tom Miles, a resident of Brighton. Assume the shares offered were unattached and surplus shares; did not inform witness of any other transactions.

Land under the Burlington has not been irrigated to highest efficiency. If statements in Exhibit 44 showing 15,000 acres irrigable under the Burlington ditch, and in Exhibit 40 showing 14,940 actually irrigated, are correct, there is a limited market for Burlington shares. The market price was stimulated four or five years ago because of pending deal between the Burlington ditch and the Denver Reservoir Irrigation Company; arrives at acre price by dividing $100 per share by four; this does not cover any water from the Oasis reservoir, refers only to direct-flow rights. Thinks that the holders of rights in Barr Lake, using water therefrom, make less demand upon the direct-flow rights of the Burlington ditch, and thereby improve the other direct-flow rights; does not know
837 whether there are separate shares of stock in Barr lake; all values assigned by the witness have been to direct-flow rights.

Outside of the Burlington, does not think any great amount of water could be bought at the values stated; there seems to be a number of Burlington shares on the market; has personal knowledge of the market value of shares of the Farmers High Line; most recent sale known to witness was in July, 1914, when two shares were sold. There were originally 1,100 shares in the Farmers High Line, but it was increased six years ago to 1,250. July sale was at $1,250 per share for unattached shares, sold apart from the land. The

superintendent of the ditch bought two shares through witness' office, so witness knows of the sale of a total of four shares, but is informed that no shares have sold for less than that, or for more.

Thinks four years ago eight shares sold at $1000 per share; price has been gradually advancing. The system is being constantly improved. Has been informed that the shares will carry as high as 18 inches. Originally the company was incorporated for $110,000, par value $100 per share, stated to carry 10 inches. Knows that at the present time a share carries more than 11 inches; does not know what the old rights recently purchased by the company aggregate; does not know that the total quantity so acquired was 6 second-feet; very large percentage of users under the system have private reservoirs.

The East Lake project, eliminating waste land, has 1450 acres of cultivated land; the East Lake company has 41 shares of the Farmers High Line, together with certain undecreed storage rights; the reservoirs are being filled from the Farmers High Line stock; including the actual land consumed by reservoirs and the construction of the same, with ditches, and so forth, price would equal $40 per acre-foot; this makes a cost of $65.70 per acre, consisting of one and three-fourths acre-feet direct-flow and three-quarters of an acre-foot storage, this arrived at by considering direct flow at $32.85 per acre-foot and stored water at $40 per acre-foot; this stored water being merely storage of the direct flow on the shares; thinks such a storage is protected by the decree; there are certain storage rights connected with the Farmers High Line Canal and Reservoir Company; the storage rights are a part of the water rights represented by the shares; there is an outstanding indebtedness, but the stock goes on the market without considering any indebtedness, and pays $5 a year per share to a sinking fund, in addition to the maintenance charge, which is nominal.

The Poudre systems referred to are situated in a higly developed section; in one system there may be both direct flow and storage rights separately acquired; did not make any investigation of the market price of storage water and storage rights, and could
838 not say what they would be except in connection with the Terry Lake right.

Knows of no actual sales under the Larimer & Weld at $4000 per share, but thinks he was reliably informed; those direct-flow rights require supplemental storage; a Terry Lake right is $2000 per share; does not know how many shares there are in Terry Lake; does not know how much water a share represents, except that it is sufficient for an 80-acre tract; does not know the assumed draft on Terry Lake, or the average delivery; has not the data from which to arrive at the acre-foot value of Terry Lake; in regard to Larimer County canal, does not know what the storage reservoirs of that system are; does not know what the delivery is therefrom; cannot tell the market value per acre-foot of storage rights, and did not investigate the question. Larimer County No. 2 irrigation system is near Fort Collins; will not attempt to locate it; it; is a combination of direct flow and storage; does not know whether both classes of

rights are carried by the same shares; he basis the value of $50 per acre-foot on the yield of the combined rights; does not know the market price per share; does not know what reservoirs the canal gets storage from; got information from Mr. Nelson, but did not get information of quantity derived from the storage rights; has made no investigation as to reservoir rights separately.

The Consolidated Hillsboro is direct-flow supply.

Arrived at the yield of 50 inches per share from general inquiry, and arrived at the information that one share is sufficient to irrigate 80 acres from various farmers connected with the system; has some knowledge from personal observation, and would say that a share gives an adequate supply throughout the season for 80 acres; has no knowledge or information of any sales at $1,800 per share.

Had information that shares had sold at $3,000; no shares were offered to witness at $1,800, and witness does not know who has them for sale at that price; took the price of $1,800 to be the present market value possibly within the last few months or a year.

Thinks 153 second-feet is the decreed quantity to the Consolidated Hillsboro; there is no storage supply.

Home Supply ditch has both direct flow and storage; one share will irrigate 10 acres market value, $400 per share, derived from what witness considered reliable information; got no specific instance of sale; except in 1912 there were sales at $450 per share; one share sold in the spring of 1906 for $525. Thinks the market price has decreased.

Did not go into the value of the storage rights.

839 Attention of witness called to Mr. Taylor's testimony, in which it was stated that the shares of the Home Supply ditch were in groups of ten, ten shares being denominated a right. Witness disagrees slightly with Mr. Taylor, his information being based more on former knowledge.

There seems to be a difference of opinion among the different informants that witness and Mr. Taylor had recourse to. Informants did not always confirm each other. Witness has not bought or sold storage rights in reservoirs in the vicinity of Denver separate from lands. Experience has been with lands and water rights attached. Union Central Insurance Company does not make loans on water rights separate from the land.

In loaning money it is necessary to make careful inquiry into the value of water rights. Is willing to concede that the Cheesman and Marston water rights on the basis of Mr. Nye's hypothetical question would be worth $50 per acre-foot delivered at the headgate, but would like to have it understood that the maintenance charge must be reasonable.

Witness' estimate represents value of Cheesman water delivered at the intake of the ditch through which it is used; is not qualified to make an estimate of the losses in delivering water from Cheesman to the intake of the ditch; knows that the Platte river from Cheesman down the south Platte, has a rocky bed; does not think the loss at that point would be great, but there is always a loss arbitrarily allowed by engineers.

Estimate was based upon assumption that the amount to be furnished from Cheesman and Marston would aggregate 90,000 acre-feet per annum, possibly 100,000 acre-feet, and had in mind that the disposition of that amount of water would be a long-drawn-out operation; did not necessarily consider that the placing of that much water on the market would depreciate values, but figured the time it would consume; the latter fact did not affect the value. By "supplemental supply" witness means where ditches had a certain direct run and not quite enough water, or where territory was being brought under more intensive cultivation. Knows that in a physical sense there is a large irrigable acreage under the English High Line, amounting to 90,000 acres, but did not consider the larger acreage in connection with a supplemental supply.

Considering the East Denver Municipal District extensions of the High Line, there are now 90,000 acres of land that could be irrigated under it, for which it would be unnecessary to make additional construction. Witness' estimate of difference in value between supplemental and sole supply was not entirely based on additional cost of construction; the water would not be worth as much as a
840 sole supply on raw land a greater distance from Denver as upon the lands upon which it could be used for supplemental supply; the duty of water has considerable to do with the answer.

Is ready to say that a large part of the Cheesman supply would be supplemental. The estimates made by witness on the Lake Cheesman and Marston supplies are strictly confined to irrigation uses; has no knowledge as to the value of the water for domestic supply for the city and county of Denver.

Redirect examination by Mr. Nye:

In putting an estimate of $50 per acre-foot on the Cheesman and Marston rights, witness considered that the purchasers of such rights would have a proportionate interest in the reservoir constructions.

FRANK J. MEDINA, a witness for the defendants.

Direct examination by Mr. Nye:

Resides in Denver; came here first in 1880; has been a constant resident for 25 years; is in the land business; represented the D. R. I. Company in the sale of water in 1908; sold company stock, which carried with it a certain amount of water; went to the farmers under the Standley lake; first work was in the territory on the west side of the Platte river and north of Denver—between Denver and Broomfield—served by Standley lake and Marshall lake; sales were made to the owners of land; later sales were made to districts; the Denver-Greeley district was organized in February, 1909; did not make the same effort to sell to individual owners after the districts were organized; there were four or five agents continuously at it; sold water at $50 per acre-foot for delivery at the farmers' headgates in the main ditch; thirty shares would cover all that was sold to individuals. The irrigation districts were organized to dispose of the stock to the individual land owners in the district.

Sold water to the district in exchange for bonds. Bonds had to be sold at a discount. In the Denver-Greeley district there was 62,000 acres, each acre entitled to five-eighths of an acre-foot; this made about 4,000 shares. The Denver-Greeley district is as large as all the other districts put together; there were not 100 people in that district; there were only 9 votes in the organization; it was a dry country; there were some people in the St. Vrain district and some in the North Denver district; the North Denver district consisted of company land almost exclusively.

841 Milton Lake capacity is supposed to be 42,000 acre-feet; thinks there are about 18,000 acres under it, including seepage land; was with the D. R. I. Company from July, 1908, to July, 1911, with one absence, and then remained until April, 1914; had charge of the water and the rights of way; during that time sold 8 or 16 shares to the same man.

Made an active effort to sell the water; have recently made efforts to sell water under Milton lake; offered stock at $400, or $40 per acre-foot; did not sell any supplemental supply. Had excursions, entered into correspondence, and followed up the correspondence; and sold water to people in Iowa, Missouri, Kansas, Nebraska, Utah, Oregon, California, Arizona and New York; at the time commenced selling rights, practically no construction; and witness continued until Standley lake was completed.

Market was best in 1909, when the districts were organized, about the time of the real construction work; after construction completed, market was not good; thinks the boom had busted; the excitement of construction helped in the sales; the enterprise looks better during construction than it does after construction; $50 per acre-foot was the gross price received by the company; rights sold on time; never got any cash; took bonds in exchange from the districts; sold under water rights purchase contracts; provision made for first payment and security for the balance, in the shape of trust deeds or mortgage on the land; lately the policy has been to hold the water rights as security; the terms on which some were recently sold were one-tenth down in cash and the balance in annual payments; early sales did not have a payment down.

Cross-examination by Mr. Dorsey:

Milton Smith was one of the promoters and stock holders and officers of the company; that period of stock sales beginning February, 1909, was about the time of the organization of the district, and continued until June, or thereabouts, of 1910. Don't know what was done during receivership; went into the hands of receiver June 6, 1910. The campaign which preceded receivership was an effort to sell stock to individuals. At that time Standley lake was being constructed. Took farmers over to see the work. Joe Osner was there at the time. The first campaign was in what was known as the North Denver district, water to be supplied from Standley Lake and Marshall Lake—the larger part from Standley—and was proposing to farmers that they mortgage their land to buy rights to be supplied from the reservoir, which had not been completed, and

the only definite knowledge on the part of the purchaser as
842 to how much water he would get for each share of stock depended upon what was told him by the agents; some evidently believed in the estimates where they bought the stock.

Had statements of the amount of money that was to be put in, and the contracts had been let to substantially our estimate, but had not then let the big contract to Kennifick & Quigley; shares were supposed to represent 10 acre-feet; there was no guarantee of water; no company would do that. The purchaser would receive either ten acre-feet or his proportionate share of the water in the reservoir; each share was to represent 10 acre-feet, but agents did not say what would happen if water was not there. The farmers would understand that they were merely entitled to their share in the yield in case of shortage. In 1908 was selling on a basis of 100,000 acre-feet; did not agree to sell not more than 100,000 acre-feet; had the privilege, in case water supply was increased, to sell more; the estimate of 100,000 acre-feet was backed up by Marshall Lake and Standley Lake capacity; actually sold shares with the understanding that Standley lake would produce 100,000 acre-feet; does not know that it was represented that Standley lake was to be 100,000 acre-feet; did not sell more than two or three thousand acre-feet; reserved the right to use Standley lake for lands on the east side of the river, but used the other lake instead, and afterwards got Milton lake and enlarged Barr lake; water has been sold on the east side; that is to be supplied from Standley—one very large quantity. Gave people to understand that Barr Lake and Milton Lake would supply water on the east side, and that they should look there for their water; the sale to the Henrylyn was made after the receivership.
